WEBVTT
1 00:00:01.883 --> 00:00:02.883 <v ->All right.</v>
2 00:00:04.054 --> 00:00:08.160 In the interest of time, let’s go ahead and get started.
3 00:00:08.160 --> 00:00:08.993 Hey everybody,
4 00:00:08.993 --> 00:00:13.710 thank you so much for coming today and this week seminar.
5 00:00:13.710 --> 00:00:16.350 It’s my pleasure to introduce Stephen Larsson
6 00:00:16.350 --> 00:00:19.023 and Adria Haimann from Metacell.
7 00:00:20.160 --> 00:00:23.730 This is a few words of context here.
8 00:00:23.730 --> 00:00:25.740 We’ve talked about, we’ve had people,
9 00:00:25.740 --> 00:00:28.140 we started this semester with somebody from the hospital.
10 00:00:28.140 --> 00:00:30.120 We’ve had people from academia,
11 00:00:30.120 --> 00:00:32.940 we’ve had people from pharmaceutical companies.
12 00:00:32.940 --> 00:00:36.750 And so very excited to present something different.
13 00:00:36.750 --> 00:00:40.320 So Metacell is a company that works
14 00:00:40.320 --> 00:00:42.657 in sort of the research space.
15 00:00:42.657 --> 00:00:44.160 Near and dear to my heart.
16 00:00:44.160 --> 00:00:46.410 They’ve been, from their beginning, I think,
17 00:00:46.410 --> 00:00:49.923 very active in the computational neuroscience community.
18 00:00:52.044 --> 00:00:56.010 We both contributed to a project called Net-
19 00:00:56.010 --> 00:00:59.763 PyNE for building models of computational neurons.
20 00:00:01.883 --> 00:00:02.883 <v ->All right.</v>
21 00:00:04.054 --> 00:00:08.160 In the interest of time, let’s go ahead and get started.
22 00:00:20.160 --> 00:00:23.730 This is a few words of context here.
23 00:00:23.730 --> 00:00:25.740 We’ve talked about, we’ve had people,
24 00:00:25.740 --> 00:00:28.140 we started this semester with somebody from the hospital.
25 00:00:28.140 --> 00:00:30.120 We’ve had people from academia,
26 00:00:30.120 --> 00:00:32.940 we’ve had people from pharmaceutical companies.
27 00:00:32.940 --> 00:00:36.750 And so very excited to present something different.
28 00:00:36.750 --> 00:00:40.320 So Metacell is a company that works
29 00:00:40.320 --> 00:00:42.657 in sort of the research space.
30 00:00:42.657 --> 00:00:44.160 Near and dear to my heart.
31 00:00:44.160 --> 00:00:46.410 They’ve been, from their beginning, I think,
32 00:00:46.410 --> 00:00:49.923 very active in the computational neuroscience community.
33 00:00:52.044 --> 00:00:56.010 We both contributed to a project called Net-
34 00:00:56.010 --> 00:00:59.763 PyNE for building models of computational neurons.
35 00:00:01.883 --> 00:00:02.883 <v ->All right.</v>
36 00:00:04.054 --> 00:00:08.160 In the interest of time, let’s go ahead and get started.
37 00:00:20.160 --> 00:00:23.730 This is a few words of context here.
38 00:00:23.730 --> 00:00:25.740 We’ve talked about, we’ve had people,
39 00:00:25.740 --> 00:00:28.140 we started this semester with somebody from the hospital.
40 00:00:28.140 --> 00:00:30.120 We’ve had people from academia,
41 00:00:30.120 --> 00:00:32.940 we’ve had people from pharmaceutical companies.
42 00:00:32.940 --> 00:00:36.750 And so very excited to present something different.
43 00:00:36.750 --> 00:00:40.320 So Metacell is a company that works
44 00:00:40.320 --> 00:00:42.657 in sort of the research space.
45 00:00:42.657 --> 00:00:44.160 Near and dear to my heart.
46 00:00:44.160 --> 00:00:46.410 They’ve been, from their beginning, I think,
47 00:00:46.410 --> 00:00:49.923 very active in the computational neuroscience community.
48 00:00:52.044 --> 00:00:56.010 We both contributed to a project called Net-
49 00:00:56.010 --> 00:00:59.763 PyNE for building models of computational neurons.
through collaborative cloud-based data science tools.

So let’s welcome them.

Thank you very much. Good afternoon everyone.

I can see some of the back of your heads, so I can imagine that I’m also, you know, virtually looking at your faces.

Thanks so much for having us. I’m Adria Haimann and I work alongside Stephen at MetaCell.

And as already mentioned, today we’re gonna share with you some insights into how academics are using cloud-based collaboration tools to enhance their research.

But before I kind of begin with this, I wanna provide you with some context. So, 10 years ago I was in your position, I was studying health economics at the London School of Economics, and I had joined a research team at the European Observatory for Health. And I was relatively new to this field and kind of found myself in a Catch 22 that maybe you can relate to. So I wanted to know how can someone or a student or postdoc discover the best way to collaborate on their research and use new tools if you have fairly minimal experience, neither academia or in industry.
So that's essentially what we want to show you today and what we'd love to share with you, if you could go to the next slide, which is kind of a collection of key topics of how researchers are doing just that, while also getting the most out of their data. So during this seminar, we're gonna cover different methods that you can share data analysis and introduce you to a specific cloud-based collaboration platform that we've created called Cloud Workspaces. And then we'll run you through some examples of how researchers are using this platform, as well as how we've formed an industry partnership. And then lastly, we wanna show you kind of other ways that this tool can be used in academic settings. And then of course, we'll open it up to you guys and encourage you to ask us questions on any of these topics. So I'll hand over to Stephen now. Thanks Adria for that great introduction. And hello to all of you. I currently see you as tiny, tiny pixels on my screen because of the way this is viewed. So as much as I'd love to be there in person...
and looking into the whites of your eyes,
I’m not gonna get that chance.
But, I think we have a really good robust discussion
for you guys that I hope you’ll find very interesting.
And thank you very much again to Robert for the invitation.
So similar backstory on myself,
I went through undergraduate training at MIT
in computer science, did a master’s in AI
before it was cool again,
and then shipped off to UCSD for a PhD
in neuroscience with a computational specialization.
So very much familiar with the academic experience
and I’m really excited to share with you
some of the things that I’ve learned since leaving academia.
And one of those things has been to start this company, MetaCell,
which I basically started as I was wrapping up my PhD
and I kind of realized that I wanted to serve science
in a different way than was gonna be possible
just within the confines of academia
because I realized that I was a builder
and to build software that could,
software tools that could be useful to, you know,
tools that I would wanted to have had as myself,
a graduate student.
I would need to kind of put a professional team of folks together that, you know, really came outta industry and that are kind of high hard to higher end academia. So the story of this slide is, since then, all the different great groups that we’ve had a chance to work with, you’ll see a really kind of motley crew of logos that are present here from, you know, really, really big pharma companies like Yale, you guys are on here, other universities that we’ve had the chance to work with, and then biotech companies, med device companies that we work with some, some of the US lots internationally. And realizing that, you know, the core thing that unifies all the work that we’ve been doing over time is the way that sort of math and computation can help us understand the life sciences. So hence I come to you today in a biostatistics seminar to talk about, you know, some of the other pieces of the puzzle that go into advancing the life sciences in that way. So, let’s start with a really simple, simple example, right?
So let’s say you’re doing some kind of analysis on some kind of bio data, okay?

Perhaps in the statistics context, you’re using SaaS.

In a computational neuroscience context, you may be using Python and the Python suite of tools.

Some in the statistics field are using R open source, you know, statistics packages.

Whatever it is, you’ve got some data, you know,

maybe you’re analyzing it on behalf of yourself,

maybe you’re analyzing on behalf of your lab, the group that you’re working with.

Maybe you’re analyzing it in terms of a company.

Whatever it is,

you wanna share that data analysis with somebody else.

You’re probably gonna have to gather some history of those commands together.

Maybe it’s packaged up as a script, maybe not.

You’re gonna send that file to somebody else very often.

And then you’re also gonna wanna somehow collect the outputs of that, right?

The figures, the diagrams, the summary statistics, the result of T-tests, you know,

things like this, right?

And send that output somewhere, right?
So, you know, that is a problem time immemorial.

And you know, as long as I’ve been, you know, working in this space still, you know, it’s very common to just do this and it’s maybe send this over email, right? It’s still a practice that I’m sure you know, happens.

And so, and that’s probably just fine, you know, in many small circumstances.

But as that scales up, there’s problems of reproducibility,

there’s problems of, you know,

keeping track of who sent what.

Email is not a great file management system.

So we’ve been thinking a lot over the course of our company,

which is, we’ve been around now,

this is our 13th year about how, you know,

the cloud and the internet basically can come into that in any better way than sending email along.

And so we’ve thought a lot about, you know, what starts to happen when there’s a computer that lives in the cloud that multiple people can jump into and join.

And what is, you know, how does that work in general?

It’s something that we’re not only just us doing, right?

This is an idea that’s been there for a while.
Anybody familiar with, say Python Notebooks, right, are aware of this idea. There’s tools like Google Colab, and then we’ve even been talking to major universities, like we’ve been having a conversation with Harvard Medical School, where they’ve been working collaboration with Amazon to kind of work together with them to set up computers that are in the cloud. Similarly, of course, there’s gonna be what happens with, at your local university at like, at your local computing infrastructure. Typically that’s based around supercomputers that are there for doing like really powerful computations or calculations. Things that are very data intensive. A workspace in the cloud is sort of in between. So it’s kind of like, you know, just a laptop that isn’t your physical laptop, but it’s like a laptop that’s somewhere else in the cloud that you can log into and do some analysis with. And it basically lives as long as you wanna do that analysis and then it goes away if you don’t need that analysis anymore.
or it can stay there as long as your lab is around, right?

And then go away if you don’t need it anymore.

So the idea is then in this story, instead of just gathering the history of commands,

sending the file and sending the output of the file,

what if, right you could do all that in the context

of a computer that multiple people can join and look at, right?

Work in that same environment.

When you log out,

it’s exactly where you left it, right?

Like if you know your computer gets misplaced or you drop it, you know, off a bridge into a river,

like, doesn’t matter ’cause

all this stuff is preserved, right?

So, how does that idea start to change the basic practice

of interacting with data and doing analysis like this

if you were to change that one variable okay?

So that’s sort of the starting premise for our chat today.

So, you know, what that might look like is, you know,

a session one-on-one or two-on-one with multiple people

where you get, you know, perhaps one of you in the future.
In the case that we’ve been doing in our company, one of our staff members, who has experience in doing a different kind of data analysis. In our case, we work on a variety of problems, but one of the major ones we worked on is like the imaging of calcium signals in neural tissue okay? But you know, you might be on a call like this one and just the same way that you might meet with your lab members on a Zoom call, you might meet with someone with experience in data analysis or biostatistics that is not in your lab or not in your even organization. It might be somewhere remote, maybe at another university or in a company like ours. But what they might get as the experience of that is jointly logging into this workspace that lives in the cloud. And if SaaS is the thing you wanna use, you might find a whole SaaS instance there in a desktop that you can log into. But the point being that multiple people now can type on it as opposed to like physically handing your laptop around in the lab or even just screen sharing it in some kind of a lab meeting, right?
It’s actually allowing for people to jump into the same application and literally like trade off on like typing commands into it. Kind of like what you get with a Google Document or a Google Spreadsheet, right? That real-time collaboration, but now for any kind of application. So that’s one experience you might have. Not just SaaS, right? So a Jupyter Notebook, as I mentioned before, another thing that you can use. And those of you who might be using, again, the more open source technologies, if you might be using R Statistics or using Python if you might be using R Statistics or using Python. or whatnot, you’d be familiar with, you know, a Jupyter Notebook. So it’s based around, you know, this idea of putting a computer in the cloud, multiple folks logging into it, and then being able to sort of transport your expertise around the world. Because in addition to the knowledge of doing analysis being shipped around, data can also come into this workspace as an intermediate space that’s private to a given lab, but allows for a different kind of model on sharing data.
where it sort of stays under the control of the lab,
you know, whoever puts it there can take it back,
that kind of thing.
Okay so we’ve been exploring this model
and we’ve also been talking to other organizations
and universities about this model and how to use it,
how to implement it, right?
As I mentioned, we’ve been talking to folks like
at Harvard Medical School that partner with Amazon
to bring these sorts of instances into their labs and what can be done with it.
So I’m gonna wanna talk a little bit about like some of those details,
and I’m saying it here in the context of our product,
but I’m not trying to sell you anything.
I’m really trying to talk about it
more in the context of what can be done.
So thinking about it, like,
so I mentioned SaaS as an example.
I mentioned Jupyter Notebooks as an example,
but there might be other kinds of software
that are more particular to a use case,
like MATLAB’s another one that could be installed.
But there might be even more specific software
that might need to be set up or run.
Sometimes, for example, survey software where you might collect data from a very particular kind of survey system and you need something to work with it. So imagine that, like for the use case that you might have, right, you could have a workspace that is set up so that all that software comes pre-built once you set it up. Much like, you know, having laptops that have come pre-configured with a certain set of tools, but instead of handing out physical laptops, it’s on the cloud. The virtual collaboration, I think I’ve gone through a lot, the multiple workspace, I think I mentioned also. Data security I kinda mentioned, you know, anybody who’s doing data analysis with anybody who has, you know, talking to somebody that they weren’t the ones to collect it, I’m sure has run into challenges where folks are reticent to, you know, share data. So that’s why in this context, it’s really important to note that like, you know, we can lock that environment down and make sure that only the people that can log into it.
have access to it, that’s a really important point.

So it’s not really like the data are going out of somebody’s control. Again, they’re kept in a place where anybody who wants to can remove that data again and delete it. And then if there were to be very computationally aggressive things to do, it’s very easy to scale it up. And that’s something that folks also like. So how, you know, how are ways that this kind of workspace can support biostatistics research and data analysis in general.

So this would be the case where any organization who says doesn’t have biostatistics or data science expertise local to them might be interested in sort of renting time or having some part-time person come in to help with that. And that’s a model that we’ve seen work well both for labs and for companies. One way in which labs really like it is new PIs with a startup package that just, you know, first few weeks into their appointment with an R one, right, no staff yet. Nobody, but they’re coming in with data from their previous, you know, from their postdoc basically.
And what do they do, right?
They need to write grants, they need to like hire staff,
they need to do all these things.
So we’ve actually found labs are very happy
in that circumstance just to get going, you know,
Hey, I have this data, I haven’t analyzed it yet.
I really wanna put in my grant proposals.
I just need somebody to kind of sit with me virtually
and run through this data,
so that I can get these figures
made and get my grant out, right?
And I just don’t have time
to bring on a full person to do that.
So data sciences service can be very useful for that.
Data standardization and sharing as a service.
So, you know, I’m not sure how much it’s affecting folks
in the room, but the NIIH over time
has gotten increasingly serious about making data sharing
happen for real for real,
and not for fake for real, right?
And so this year in particular,
a new policy from NIIH has come out, DMS policy,
where they’re really, really asking for even, you know, grant proposals to have a whole data manage-
strategy figured out upon submission.
And even, you know, saying you need to set aside
some budget for that
'cause it turns out data sharing doesn’t happen for free,
doesn’t happen for free, you know,
for PIs for their time, right?
So that’s also something where, okay,
I don’t have the expertise to figure out
which of the billion databases I might share my data in.
Could somebody come in and help do that?
Well how do you do that?
You know, when I did work in the neuroinformatics
space as a graduate student
and I was trying to help figure out for neuroscientists
how to get data that they had, you know, collected
in a very laborious process of experimental collection,
was trying to help them share their data
'cause they wanted to comply with these policies
even back then, you know, very frequently I would
get the challenge of like,
"Yeah, it’s in a hard drive under my desk, right?"
Physical hard drive sitting under my desk, right?"
Like, okay, so you can go pick it up and like take it away
and do something with it.

But you know, they don’t have the expertise, you know,

locally to even know, okay, now we’re gonna plug it in

click through it

and like, oh, the PhD student is left three years ago.

And like, how do I do that?

So the idea of, okay, if all we can do is like take that

hard drive from under the desk

and like plug it in the cloud, share it on Dropbox,

okay, something like this or you know,

have a conduit to get it to the cloud,

share that folder in a workspace online

and then have somebody else that does this all the time

like go through all that and do their best to start,

you know, documenting what they find,

maybe raising questions that they might find,

you know,

to present to the PI,

"Hey, I know your PhD student left three years ago,

but you know, can you tell me a little bit

about this experimental methodology?"

There’s now at least a hope that you can start,

you know, standardizing that data,

sharing it in a better way,

making the NIH not come kick down your door
with the data sharing police force
that I’m sure they’re setting up now.
Okay probably not.
Okay a third way is through workshops.
And I’ll have some specific examples
a little bit later about this one.
But if you think about, you know,
the experience of either physically traveling
or doing what we’re doing here
and then being exposed to software, right?
It’s one thing to have slides show
you pretty pictures of what software looks like.
And it’s another thing to say basically like,
"Hey, log into, like go right now on your laptops
and go hit this address"
and while I’m explaining it
here’s your login and like while I’m explaining it
to you, check it out, play with it, right?
So we’ve actually found that also to be a really valuable
way to do an extra level of education and demonstration,
especially for tools built in academia,
which generally have a pretty small audience, right?
Not a lot of people use them maybe necessarily,
or it’s like a very niche community.
So the total number of humans is not great.
So to have the ability right now in a live session
to be like, let me show you this software you log in right
now, play with it can move the needle a lot on getting folks
to use stuff that that there will really be tools
that they will actually help them a lot.
And then lastly, you know,
collaborations between labs, right?
Hey, we just set up a consortia,
it’s a five lab consortia
and we’re all studying this thing, right?
It’s a collaboration between the folks that are generating
the data and the folks are gonna analyze the data.
Okay, great, we got this really smart set of mathematicians
who are gonna do all these great statistics, awesome.
How do you get the data from point A to point B?
Well email, right?
So what if you can improve that, right?
Or you know, the context of, you know,
we also find companies wanna collaborate with each other’s
and then universities and companies wanna collaborate
with each other also, right?
So in ways that I haven’t already listed,
but just collaborations of whatever variety.
So when it comes down to those things, right,
it’s one step better than just sharing on Dropbox
and being like, here are the data, go check it out 'cause you’re keeping the analysis all together, right?

It adds a layer of reproducibility to those kinds of collaborations, which are hard to match in addition to all the other things, all the great best practices for reproducibility.

Okay so that’s four ways to use cloud workspaces support biostatistics research.

So let’s, you know, I think I’ve kind of walked through this example already verbally, but I did have a slide specifically for it. So like this happens in research all the time. There’s a lab that needs a particular analysis completed and they don’t have the expertise in lab.

What can be done? So typically the alternatives are, you know, bring in some student or a postdoc or collaborate with a lab that has some mathematical expertise to perform analysis.

But that can be quite time consuming, you know, that might not deliver the results you’re looking for. Secondly, right for folks who might, you know, be in a position, like I mentioned with early lab set up, right?
Engaging some part-time data scientists from industry could help work on particular problems as needed. And that’s interesting both perhaps from the perspective of me as a company, but also maybe interesting for yourselves thinking about a path through industry where you might be able to do biostatistics for multiple organizations at once, not just one at a time. And then it’s also interesting, as I mentioned from the perspective folks that have the problem that need to get the analysis done. Okay so some case studies, does this happen? I sort of mentioned abstractly, it does, but these are five cases that we’ve worked on in our company and they are, many of them have a, well they all have the theme of being calcium imaging data, okay? So here, you know, swap out biostatistics for looking at data that comes from a microscope. But at the end of the day, that data from a microscope is basically a video stream, generally black and white images that then have to be post-processed. And from that video stream there’s a spatial component of looking at a field of neurons under a microscope.
and a time component.
Like how did those, you know,
neurons activity change over time.
But there’s a lot of like statistical challenges
that have to go into that.
You need to separate the neurons out from
each other, okay?
They kind of overlapped on each other.
So looking at a video stream, you’re not always
sure, right?
If I’m looking at one neuron or two neurons.
So you have to do some spatial analysis
to separate those out.
And then you wanna do some sort of peak
finding over time.
What you kind of wanna extract out is a time
series of however many neurons you’ve detected
in your field of view
and then start to do some additional analysis.
And that additional analysis will be based on
the specifics of the experimental setup
and like, you know, what part of brain were
you looking at?
What was your protocol that you applied
and what kind of expectations
do you have about the time series that you
extracted?
So these organizations that we work with, I
guess, you know,
four out of five are universities.
So DGIST is Institute of Science and Tech-
ology
And then Maze, which is a small pharma company in San Francisco and they’re all doing calcium imaging work.

And I think we served all of these organizations within the same span of about six months. Each one of them had brought different data to the table. They’re all generally in this form of video data with the calcium imaging to extract. All five of them were served by the same data scientist on our side, gentleman whose picture you saw earlier but they had very different scientific protocols, right?

So it wasn’t necessary that one person full-time over six months worked on each of these projects, right?

Instead we have one individual, who’s able to jump from project to project and check back in with multiple PIs/business leaders, managers to check in on the results of that, right?

And that person never left their home, right? So our company is also fully remote, which is nice.
of what’s possible for this kind of analysis, whereby, you know, essentially organizations in multiple different countries and different continent in one case, right, can all be served by the same person doing roughly having roughly the same skillset of data analysis but working on data that addresses very different scientific questions all at the same time. Okay, so that’s a thing. And, in each one of these, I should say where there’s one workspace per organization, right? So each organization has their own workspace, they log into it, they can see the results of the data science work that happens. They have all in one way or the other, put data into the workspace, right? And, they’ve all sort of been able to pull figures back out again and direct the flow of analysis in the direction that they wanted through Zoom calls, generally on like a weekly basis or every couple weeks check in. So yeah, a little bit more about the team behind that in terms of thinking about like what it takes
to make that happen.

While there is a little bit of like finding those labs and figuring out that they have that problem, which are not taken care of by the individuals on this screen.

But I mentioned, I mentioned Phil, the PhD; another PhD, who’s worked with us as data scientist is Marcus. And then kind of orchestrating behind the scenes, the standing up of these workspaces is a software architect, Zoran. Phil in the New York area, New York City area. Marcus is in China and Zoran is in the Netherlands.

So again, interesting to think about the different geographies where folks come from being able to serve people in different geographies,

but all of them when it comes to a project, like the center organizing node is a workspace. That is the thing that helps coordinate a lot of this together.

There are a few other technologies that help. Those of you familiar with like a Kanban board or just really any kind of task driven software, you can bring that to bear as well.

So one of the ways you can organize work a little bit better
than just sending emails back and forth is to encapsulate each task, break each task down into a card on a Kanban board. We like the tool called Trello, but there’s lots of them out there that can be used for such things. And then, you know, one card per task is a nice way to organize things. And then using a practice from software engineering, you can actually sort of estimate in roughly how many hours, you know, the data scientists might think it would take to do a given task and then use that as a way to figure out like how long it’s gonna take to do a certain kind of analysis. This is a practice that we actually use across my company for all sorts of tasks, not just data science, really organizing kind of everything that we do on the basis of making cards like this and moving things across. And I’m still surprised how many organizations don’t use this. I have lots of friends in academia that do this just for their labs. You guys might do this in your labs, I don’t know. But for organizing oneself,
even if you do meet in person, having this sort of set up in the cloud can be very helpful for organizing work. Not sure how new or not new this is to those of you in the room, but something we use. And then of course there’s Slack, which I think has pretty good adoption amongst academia. We do find almost every lab that we talk to pretty much is on Slack or some version of it. Companies are using Microsoft Teams, which I personally like less, but you know, but we use that too. But basically, you know, one thing that we do that maybe others don’t do is to connect a Kanban board like the one that you saw to spit out notifications in a Slack channel at the same time, which can be really nice if you are a Slack based person to just like be able to see how tasks are changing and evolving in the feed, which then doesn’t require an extra conversation, right? Like "Hey, so we agreed on Monday that you were gonna, you know, do that t-test on this survey data, how’s that going right?" Well if they’ve moved that card,
which was like T-test on survey data from the to-do column,
to the doing column, a little notification’s gonna pop up in Slack. And then when they write a comment like, "Yep, you know, I ran the test and wasn’t statistically significant,”
then that’s gonna pop up also. That comment will then be relayed into Slack. So then when you go back to check in,
you don’t have to ask that question. It’s like, "Yep, I saw that it happened and by the way I saw that it happened on Tuesday,
you know, now it’s Wednesday, you know. I forgot to check back in with you about it.”
So like that idea of asynchronous work can happen in this cloud-based context also, which again,
like we use also in all other parts of our company can be really helpful for moving projects along in lots of ways.
So yeah I’ve told you a lot about a particular example then of doing work.
I wanna call Adria back in here to extend a little bit more in a partnership example that we’ve had some experience with.
So back to you Adria.
Thanks, so one thing that Stephen mentioned was, you know,
another challenge we might face is,
okay, where do we go find people who have data that
they might need help with?
And we were thinking about where does data come from, right?
And so one area that data’s generated from is through devices and manufacturers
make devices that are sitting in labs.
So we thought of the idea of let’s have discussions
with these manufacturers
and see if we could form some sort of partnership.
Now when you’re forming a partnership in industry,
you need to think about why that would benefit both sides
in order to kind of engage your perspective partner
as to why they should talk to you right?
So one thing that we identified was that
a key aim of manufacturers
to provide additional support
to their customers or make sure,
hey, I have a customer or a lab that has data
and then what if there’s an aspect of their data
do not know how to do something
or they don’t know what to do,
maybe they’ll stop using my device down the line
because the data’s just not useful to them at this point
'cause they're lacking a skillset. So we thought of an idea whereby we could approach device manufacturers and kind of explain what Stephen explained about our data science as a service offering and say, "Hey look, we could form a partnership with you, whereby as an offering, in addition to extending a warranty on your device, you could offer custom analysis support or data science support to any interested customers, whereby they could use cloud workspaces to put their data that they're collecting and then they could work with someone like Phil to solve a challenge that they might have.” And so we actually successfully did form such a partnership quite recently. And if you go to the next slide, you'll see, so we are now working with a company called Neurophotometrics. They produce a device that does the imaging that Stephen previously described. And what our partnership involves is we essentially offer cloud workspaces as a solution to their customers, whereby when they collect their data, they can then work on our cloud workspaces alongside Phil or ourselves and we can work with them.
to solve any challenges they might need.

Now who are these customers of Neurophotometrics?

They are a bunch of different labs kind of all over the world as well.

Mostly academics, some in industry as well.

And so it’s that way for us as an organization to kind of find potential labs we didn’t even know had the challenge.

And then it’s also solving the problem for NeuroPhotometrics of how do you keep your customers happy if you don’t really offer a service they’re already kind of asking of you as a follow-on for providing this device.

So, so far the partnership is fairly new. It seems to be working quite well so far and we’re meeting new people and already getting kind of more projects like Stephen described for Phil to work on. So we’ll see how it goes.

But this is just one way to show you that it’s not just about kind of solving a problem for a customer, it’s about where do you find your customers and that could be through an industry partnership.

Awesome, thanks for that.

So I mentioned one other model earlier, which is workshops.
And we have done a few of them actually as well in the computational neuroscience space.

So now the space near and dear to our work with Robert.

One of those projects was a collaboration actually Brown University on something called the Human Neocortical Neurosolver.

We have kind of a neuroscience bias in the company.

We like doing those sorts of things.

We did a workshop also.

We helped facilitate a workshop that allowed a software tool that came out of this particular collaboration to be shown.

And, let me show you a little bit more.

In this case, I’m actually gonna switch away from the Human Neocortical Neurosolver and also show you an example with NetPyNE, which is the thing that Robert mentioned earlier.

That we work with as well.

It’s similar to HNN.

In both cases there’s a computational model of a neuron, okay?

Just think of like, you know, a spatial model of a neuron that has a cell body and an axon and dendrite, that kind of thing.

And you wanna simulate something about it.

And so you have a specialized piece of software
that knows how to look at the model of a neuron,
the way that it’s shaped,
and how to get signals out of it basically, right?
So in collaboration with NetPyNE also a software platform
called Open Source Brain at UCL
that we’ve been partnering with for a while.
You might have something that looks like this.
So what you can do in a workshop context
with something like a workspace that’s really exciting,
as I mentioned to you before is have people put hands on with the software itself.
And this is one of those pictures from one of those workshop that we did,
I think this one was specifically NetPyNE
where you can kind of see what everybody’s looking at.
So everybody brought laptops in, right?
And they’re able to launch in this case
you can see several of ’em,
like this one up in front and this one over here,
they literally have exactly the same screen up
that is being shown, you know, in the screen share,
not because they’re logged into a Zoom,
but ’cause they’re actually logged into essentially
a workspace environment where they can also like, you know,
change parameters around.
So you can get this hands-on tutorial effect in a workshop, in this context. That is kind of hard to do any other way if you don’t have that. If it’s deployed as web-based software, that makes it a little bit easier. But if it’s not, you know, if it’s something that’s traditionally supposed to be on a desktop, then this is kind of the only way to do something like that. And this was at a academic conference, I think CNS that gets held. And this was at a academic conference, I think CNS that gets held. So yeah, from all that today then kind of wrapping up the part where I just, we just talk at you and I hope those questions that you guys have, what do we sort of talk about today? Like how can some cloud-based data science tools help enhance the ability to do biostatistics health informatics research? I’ve been, you know, leaning on some examples that are heavily neuroscience based, but we kind of think that that’s not the thing that’s particular to this, right? It’s still, you know, as I started at the beginning, you know, doing some analysis, you know, sharing the results of the commands that we’re using in the analysis.
and then sharing the output of that analysis, right?
Like that’s where we began.
I think that’s common to every technique.
We’re bringing some kind of science and math to bear on some data, right?
So what we’re finding is that, you know,
by using cloud-based platforms really can help us facilitate collaborative research,
allowing colleagues to share data and work together.
You can help labs efficiently gain access to additional data science support if that’s desirable.
That they, you know, otherwise might struggle to get or is just kind of unaffordable.
Doesn’t make sense ’cause there’s too much of a person.
And then finally in the last example, right,
you can facilitate, you know,
distance workshops that allow much more immediate hands-on experience with certain software.
So with all that, I will thank you all for listening
to us for a full 40 minutes and happy to take any questions that you have on this
or any other thing I can help directly.
Thank you very much.
Thank you so much.
Does anybody have any questions for our presenters?

I’ll start if there’s no questions.

So data science is a service growth industry. People want jobs.

What’s your take on the industry on that?

We are about 18 months into our exploration of the market.

We have seen growth so far.

We think there’s more to go.

I showed you those five labs, I think in total maybe served certainly more than a dozen,

I wanna say maybe like 15 and like labs plus companies or so

15, 16, in those 18 months.

We had to figure out lots of other stuff along the way.

We think there’s a need, you know, like I mentioned

and folks that have the skillset to, you know,

provide that data science service

that are continually in demand.

So I’m gonna say yes, it’s growing.

We’re always wondering in industry how fast, you know,

that’s always the question,

but it’s definitely not shrinking.

Alright, that’s an exciting option.

Yeah just really quick,

what happens with authorship?

If you work with the lab very closely on a project,
they come out with a really good publication.

How do you deal with that in this industry?

Yeah, great question. Thank you.

So as a company,

do we require to have our data scientists listed

as co-authors on papers.

I think from an ethical perspective

in the case where the contribution that the data scientist

has made are very significant

you know, sometimes PIs have asked the question to us,

you know, sometimes PIs have asked the question to us,

what sort of acknowledgement

would you like of the data scientist?

And if the PI feels that, say, you know,

someone who has a PhD who works with us

has done enough work that it merits authorship,

they’re free to add that person.

We don’t require that.

Otherwise, you know, an acknowledgements nice always right?

But also not required.

I think, you know, sometimes the nature

of the contribution really matters.

So, you know, as a company it’s a little bit

like how much do you acknowledge

the vendor of your microscope, right?

You might say, okay, I did this on a Nikon microscope

or you know, but you might write that more

as a method section.
And then if like a technician came out and like helped you calibrate it, you’re probably not gonna give that person an authorship either. But you might acknowledge them if they did extensive help that like led to some novel process. So on the whole, it’s a case by case conversation that scales based on the level of the contribution, but it’s not the first thing that we think of. It’s not like, "Hey, because we did anything for you, please put us on a paper." Definitely don’t do it that way. It’s more the opposite, which is like, you know, we’re gonna do a thing for you. Probably, you don’t need to cite us. But if it gets up to a certain point we kind of mutually agree that that’s appropriate, then we’re happy to discuss that.

Thank you for sharing Stephen. So I have a quick question too. If you’re running on data sets, one cell may take really long time to run, then how do you solve the concurrency issue? Let’s say there’s multiple people collaborating online that when the cell is running, what if some other, another party just clicked stop?
or doing something random? How do you solve the issue that people are on the same page when something takes really long time to run?

Yeah, great question. So a few ways,

one nice thing about a cloud workspace is that we can expand the number of processors and the amount of memory kind of behind the scenes transparently. So basically you can like log out of the workspace and in five minutes log back into the workspace and we’ve like doubled the processing speed and like doubled the memory.

So we tend to keep our default instance at like a reasonable like laptop, like probably not a high end.

And then when we discover cases like what you’re talking about where like, yeah, no, that cell requires a lot we kind of know a little bit in advance, like we’re gonna wanna run that a lot, right? We might do this, which was we might like just beef it up, right?

And that’s cool that we can do that.

And then the question becomes like, does that need to run, you know, 24/7, does it need to run every day, every week, every month right?
We think a little bit about that because then there’s some additional costs on our side.

If you’re gonna do it for like an afternoon, it’s like really not, it’s not worth making any additional, you know, requests of somebody.

But there’s another part of your question I wanna get at too, which is like maybe overriding each other, right?

So that can happen. And that’s a little bit like software specific. So like in a Jupyter Notebook, you could, if you don’t coordinate a little bit with your lab member, like overwrite something in one cell at one time, right? The other person didn’t notice. So for that, we have some best practices, you know.

By far the most common, you know, example that we see is, is like two or fewer people collaborating, but if it were three or four, we’d probably recommend that they do a best practice.

Of like, you know, while you’re doing work that’s separate and you’re not like talking to each other, do work on separate copies of the thing, right? And then come together in a meeting and like put it back together, right? Usually is the better practice if you’re say,
working on a Jupyter Notebook, and you know, communicate, you know, using some other method like a meeting like this. So yeah so those are the two aspects. On the one side, if it’s computation intensive, we can make it bigger. If it’s actually about people writing each other, we recommend some best practices for communicating outside of the workspace. All right, I have one more question. So like in the old days, everybody would buy a nice computer for their lab or maybe a couple of nice computers and like then everybody would log in at that and it was a one-time cost, right? And so how have you found, I don’t know, it’s a very different model for both academia industry, wherever that’s trying to transition from this one time cost 10 years later for good and ill versus sort of this continuous cloud-based thing. I don’t know, do you have any words of wisdom on this transition? Because it seems like, you know, you pay
for a cloud computer and if it’s on constantly, it eats up a lot of money.

Yeah, yeah.

So really good question.

So I think and-

Lose control of your data also, which to some extent,

In theory, yes.

But you know, I think some of this is just like a journey

and a transition that, you know, scientists are making.

Those of us, like yourself, we’re more software engineer minded,

have been comfortable with the idea of say, you know,

like all of our company’s data, for example,

is kind of in Google’s clouds,

Google’s workspace technically.

None of it is sitting under my desk, right?

But we’ve gotten a level of comfort about data ownership

based on essentially trust and agreements

and our understanding of how certain sections

of disk are like cordoned off, you know, for ourselves

and lying on some of those best practices.

But to get to the heart of your question,

I think the best metaphor is like

buying a house versus renting an apartment, right?
So, you know, going down to Apple and picking up a laptop or Dell or whatever you wanna use, right, is that’s the buy model. And we’re super comfortable with that.

The cloud model is more the like renting the apartment. And certainly people make the choice, you know, not to rent sometimes because it’s like, doesn’t work out economically, right?

It’s like, "Hey, I’m throwing money away." Sometimes people throw, right?

But what is the advantage of renting, right? The advantage of renting is, you know, if a thing breaks in your rented apartment, you call us and you’re like, "Hey, this thing didn’t work, please fix it, right?"

And then there’s this scaling thing, right? Which is like, if you go back to Apple and you’re like, "Actually can you add like double the CPU and double the memory?"

They’ll be like, yes, you can pay us for that, but it’s gonna take a while, right? And it’s not gonna happen flexibly and scalably.
1073 00:49:44.490 --> 00:49:48.241 So I think it fits into a different space, right?
1074 00:49:48.241 --> 00:49:49.710 Obviously these two come together,
1075 00:49:49.710 --> 00:49:52.470 I’m talking to you on a physical laptop that I own, right?
1076 00:49:52.470 --> 00:49:55.612 But I’m also using cloud instances to do things.
1077 00:49:55.612 --> 00:49:59.850 So I think it’s like, it fits into this niche where like,
1078 00:49:59.850 --> 00:50:02.910 actually the most useful computer for this purpose,
1079 00:50:02.910 --> 00:50:05.130 this collaborative purpose
1080 00:50:05.130 --> 00:50:08.070 is a rented one, right rather than an owned one.
1081 00:50:08.070 --> 00:50:10.560 And you know, maybe that means when I’m not using it,
1082 00:50:10.560 --> 00:50:13.110 I’m not paying for it at all, basically, right?
1083 00:50:13.110 --> 00:50:14.910 Like, if I’m like paused on this collaboration,
1084 00:50:14.910 --> 00:50:16.680 then I’m like actually not paying for it at all,
1085 00:50:16.680 --> 00:50:18.420 but then I can bring ’em back and six months and start
1086 00:50:18.420 --> 00:50:19.530 paying for it again.
1087 00:50:19.530 --> 00:50:22.410 So this is what I hope that folks take away is like,
1088 00:50:22.410 --> 00:50:24.300 it opens up a lot of new possibilities.
1089 00:50:24.300 --> 00:50:25.800 And the ones that we’ve gotten
1090 00:50:25.800 --> 00:50:26.940 are certainly not the only ones.
1091 00:50:26.940 --> 00:50:28.410 There’s just like lots more
1092 00:50:28.410 --> 00:50:30.063 that you can imagine or envision.
1093 00:50:31.620 --> 00:50:34.679 But, but yeah, it’s a mindset change
1094 00:50:34.679 --> 00:50:36.840 and it’s one that I think, you know,
1095 00:50:36.840 --> 00:50:40.293 requires some adapting, yeah.
1096 00:50:40.293 --> 00:50:43.860 <v ->All right. Thank you so much.</v>
1097 00:50:43.860 --> 00:50:45.390 <v ->I have a question for you guys</v>
if there’s not another question for me.

There’s a question on the screen.

Sorry, I have a question.

I think piggy-backing off of that question-

Hi hello. Hi Noelle.

Actually Hi.

I used to like physical like pieces of data

and like having physical hard drives.

So like what is the security for data that’s on the cloud?

Yeah, so folks like,

we ourselves build these cloud instances

on the back of three major providers,

whose names you’ll recognize,

Amazon, Google, and Microsoft okay?

Those are the big three cloud providers

and they make a guarantee to us

and then we make a guarantee to our customers

about the data protection.

So it’s kind of like a layer cake.

And the foundation of it begins with, do you trust Amazon?

Do you trust Google? Do you trust Microsoft?

Some people say yes, some people say no,

but fundamentally they are the ones that, you know,

build data centers, right where the physical aspect

of these computers actually live.

So, you know, this virtual computer,
"Hey, show me the hard drive where this lives."

You're gonna go out to like, I don't know, Washington State near some power plant basically, where it's very economical to set this up, right?

So they then guarantee like, how do you know that that's safe, right? Well they guarantee that they're following industry standards to secure those facilities, to lock them down, to like continually maintain and manage the networks that are there to patch the servers that they're using to keep ahead of any security faults.

So there's one layer of this where we rely on these big providers to do their jobs.

And despite the last 15, 20 years of like hacks that you've heard about whatnot that happened in industry, these three providers so far have managed to avoid being hacked in any major way.

Like you've not heard of like Amazon getting hacked, Google getting hacked, Microsoft getting hacked.

If tomorrow Amazon gets hacked, then yeah, we're all worried okay?

And then we probably would need to shift around.
But so there’s a fundamental guarantee that like all cloud kind of relies on and it’s like good to talk about it because like we all have to kind of trust these, you know, these large providers. But they also invest, I’d say millions or hundreds of millions of dollars in computer security. Like if you’re in the field of computer security, you know these guys because they are sort of world leaders in this sort of thing. Microsoft, you know, notably was involved in doing some forensic analysis on like Russian hacking back in 2016. Like they were some of the first people to notice that a state actor like Russia was on the scene doing the various things, taking over computers. So generally the community of software engineers that do cloud work know these things and kind of rely on Google, Amazon, and Microsoft to like make these investments in computer security. And notably, I don’t go like set up my own data center because I know that I would have to invest millions
of dollars in having an equivalently good computer security
team to like watch out for Russia, who by the way also invests hundreds of millions of dollars
to try to hack these things.
So, the world of computer security is a problem.
So there’s that level of trust, okay?
And then on top of that, you have to trust one more level,
which is the group that like sets up the workspace.
So you kinda have to trust, like if it’s from us,
you have to kind of trust us that we’re not screwing
something up on top of all of those protections
‘cause it is possible to do that at the level of like,
you know, Jupyter Notebook that our logins are well used.
So we also invest in using industry standard like login protocols, so that only the people that we say
can log in can log in, right?
There’s a layer of software security there that, you know,
we have to be on top of patching at one level also.
So these are all the things that make that secure.
And the last thing would be like,
to not go in and do something nefarious with your data
even though we’re the only ones that can control it.
So you trust that nobody else can get into it,
but do you trust us?
And then that becomes,
yeah a question of like, you know,
going back and checking your references, you know,
talking to other PIs, making sure that something nefarious hasn’t happened, you know, there.
And you probably wanna gain some confidence on that.
But what we’ve found is that organizations are getting more and more comfortable with that.
Dropbox is a publicly traded company,
lots of people put stuff on Dropbox.
When you put something on Dropbox,
you’re essentially trusting Dropbox.
Dropbox is also built on one of these three providers same way, right?
So it’s that kind of idea
that takes some getting used to but you know,
becomes increasingly useful to do this kind of work on.
And we see large banks and large pharma companies
having taken their time to also adopt cloud large financial institutions.
But over time there’s been increasing comfort as some of these security questions have been, you know, asked and answered. So bit of a long answer, but thank you for the question ’cause it’s important.

Alright, thanks so much.

In the interest of time, I think we’re gonna have to stop it here, thanks again.

Really appreciate. (audio garbles)

Thank you guys. Thank you all for your time.

Have a great day.
