WEBVTT

- $1\ 00:00:00.040 \longrightarrow 00:00:00.873$ Hi.
- 2 00:00:00.873 --> 00:00:01.706 Hi everybody.
- 3 00:00:01.706 --> 00:00:02.539 Students Hi.
- 4 00:00:02.539 --> 00:00:03.372 It's my pleasure today
- $5~00:00:03.372 \longrightarrow 00:00:05.253$ to introduce Professor Rebecca Andridge.
- 6 00:00:06.120 --> 00:00:09.920 Professor Andridge has a Bachelors' in Economics in Stanford
- $7~00:00:09.920 \longrightarrow 00:00:13.290$ and her Master's and PhD in Biostatistics
- 8 00:00:13.290 --> 00:00:14.890 from the University of Michigan.
- 9 00:00:15.744 --> 00:00:17.670 She an expert in group randomized trials
- $10\ 00:00:17.670 \longrightarrow 00:00:19.440$ and methods of missing data
- $11\ 00{:}00{:}19.440 {\:{\mbox{--}}\!>\:} 00{:}00{:}22.930$ especially for that ever so tricky case that is not,
- $12\ 00:00:22.930 \longrightarrow 00:00:25.700$ or so where data is missing not at random.
- $13\ 00:00:25.700 --> 00:00:28.780$ She's been faculty in Biostatistics in Ohio State University
- $14\ 00:00:28.780 \longrightarrow 00:00:30.620$ since 2009.
- $15\ 00:00:30.620 \longrightarrow 00:00:32.210$ She's an award-winning educator
- 16 00:00:32.210 --> 00:00:35.930 and a 2020 Fellow of the Americans Associates,
- $17\ 00:00:35.930 \longrightarrow 00:00:38.290$ and we're very honored to have a huge day.
- $18~00{:}00{:}38.290 \dashrightarrow 00{:}00{:}40.186$ Let's welcome professor Andridge.
- 19 00:00:40.186 --> 00:00:43.470 (students clapping)
- 20 00:00:43.470 --> 00:00:45.860 Thank you for the very generous introduction.
- 21 00:00:45.860 --> 00:00:46.693 I have to tell you,
- 22 00:00:46.693 --> 00:00:50.800 it's so exciting to see a room full of students.
- 23 00:00:50.800 --> 00:00:52.440 I am currently teaching online class
- $24\ 00:00:52.440 \longrightarrow 00:00:54.320$ and the students don't all congregate in a room.
- 25~00:00:54.320 --> 00:00:56.883 So it's like been years since I've seen this.
- $26\ 00:00:57.830 --> 00:01:01.400$ So I'm of course gonna share my slides.
- $27\ 00{:}01{:}01{:}01{:}400 \dashrightarrow 00{:}01{:}06{:}320\ I$ want to warn everybody that I am working from home today.

- $28\ 00:01:06.320 \mbox{ --> } 00:01:08.600$ And while we will not be interrupted by my children
- $29~00{:}01{:}08.600 \dashrightarrow 00{:}01{:}10.580$ we might be interrupted or I might be interrupted
- $30\ 00:01:10.580 --> 00:01:13.000$ by the construction going on in my house,
- $31~00:01:13.000 \longrightarrow 00:01:15.790$ my cats or my fellow work at home husband.
- $32\ 00{:}01{:}15.790 \dashrightarrow 00{:}01{:}18.260$ So I'm gonna try to keep the distractions to a minimum
- $33\ 00:01:18.260 \longrightarrow 00:01:21.530$ but that is the way of the world in 2020,
- $34\ 00:01:21.530 \longrightarrow 00:01:23.700$ in the pandemic life.
- 35 00:01:23.700 --> 00:01:25.880 So today I'm gonna be talking about some work
- $36\ 00:01:25.880 \longrightarrow 00:01:26.960$ I've done with some colleagues
- $37\ 00:01:26.960 \longrightarrow 00:01:28.720$ actually at the University of Michigan.
- $38\ 00:01:28.720 --> 00:01:31.090$ Talking about selection bias
- $39\ 00{:}01{:}31.090 \dashrightarrow 00{:}01{:}34.373$ in proportions estimated from non-probability samples.
- $40~00{:}01{:}35.690 \dashrightarrow 00{:}01{:}38.020$ So I'm gonna start with some background and definitions
- 41 00:01:38.020 --> 00:01:40.460 and we'll start with kind of overview
- $42\ 00:01:40.460 --> 00:01:43.070$ of what's the problem we're trying to address.
- 43 00:01:43.070 --> 00:01:45.120 So big data are everywhere, right?
- $44\ 00{:}01{:}45.120 \dashrightarrow 00{:}01{:}48.574$ We all have heard that phrase being bandied about, big data.
- $45\ 00:01:48.574 \longrightarrow 00:01:49.890$ They're everywhere and they're cheap.
- $46\ 00{:}01{:}49.890 \dashrightarrow 00{:}01{:}53.360$ You got Twitter data, internet search data, online surveys,
- $47\ 00:01:53.360 \dashrightarrow 00:01:56.280$ things like predicting the flu using Instagram, right?
- $48\ 00:01:56.280 \longrightarrow 00:01:59.170$ All these massive sources of data.
- $49~00{:}01{:}59.170 \dashrightarrow 00{:}02{:}03.140$ And these data often, I would say pretty much all the ways
- 50~00:02:03.140 --> 00:02:06.500 arise from what are called non-probability samples.

- $51\ 00:02:06.500 --> 00:02:08.320$ So when we have a non-probability sample
- $52~00:02:08.320 \dashrightarrow 00:02:10.580$ we can't use what are called design based methods
- $53\ 00:02:10.580 \longrightarrow 00:02:11.413$ for inference,
- $54~00{:}02{:}11.413 \dashrightarrow 00{:}02{:}13.880$ you actually have to use model based approaches.
- $55\ 00:02:13.880 \longrightarrow 00:02:16.310$ So I'm not gonna assume that everybody knows
- 56 00:02:16.310 --> 00:02:17.750 all these words that I've found out here,
- $57\ 00:02:17.750 --> 00:02:20.393$ so I'm gonna go into some definitions.
- 58~00:02:21.640 --> 00:02:25.120 So our goal is to develop an index of selection bias
- $59\ 00:02:25.120 \longrightarrow 00:02:28.450$ that lets us get at how bad the problem might be,
- $60~00{:}02{:}28.450 \dashrightarrow 00{:}02{:}32.200$ how much bias might we have due to non-random selection
- 61 00:02:32.200 --> 00:02:33.173 into our sample?
- $62\ 00:02:34.380 \longrightarrow 00:02:38.220$ So a probability sample is a situation
- $63\ 00:02:38.220 \longrightarrow 00:02:39.230$ where you're collecting data
- $64\ 00:02:39.230 \longrightarrow 00:02:41.020$ where each unit in the population
- $65\ 00:02:41.020 \longrightarrow 00:02:44.460$ has a known positive probability of selection.
- 66~00:02:44.460 --> 00:02:47.330 And randomness is involved in the selection of which units
- 67 00:02:47.330 --> 00:02:48.970 come into the sample, right?
- $68~00{:}02{:}48.970 \dashrightarrow 00{:}02{:}52.940$ So this is your stereotypical complex survey design
- 69 00:02:52.940 --> 00:02:54.670 or your sample survey.
- 70 00:02:54.670 \rightarrow 00:02:57.130 Large government sponsored surveys
- 71~00:02:57.130 --> 00:03:00.020 like the National Health and Nutrition Examination Survey,
- $72\ 00:03:00.020$ --> 00:03:04.320 NHANES or NHIS or any number of large surveys
- $73\ 00:03:04.320 \longrightarrow 00:03:05.760$ that you've probably come across,
- 74~00:03:05.760 --> 00:03:09.000 you know, in application and your biostatistics courses.

- $75\ 00:03:09.000 \longrightarrow 00:03:11.130$ So for these large surveys
- $76\ 00:03:11.130 \longrightarrow 00:03:13.560$ we do what's called design-based inference.
- $77\ 00:03:13.560 \longrightarrow 00:03:15.820$ So that's where we rely on the design
- $78~00:03:15.820 \longrightarrow 00:03:17.670$ of the data collection mechanism
- $79\ 00:03:17.670 --> 00:03:19.770$ in order for us to get unbiased estimates
- 80 00:03:19.770 --> 00:03:21.240 of population quantities,
- $81~00:03:21.240 \longrightarrow 00:03:24.340$ and we can do this without making any model assumptions.
- $82\ 00:03:24.340 \longrightarrow 00:03:25.870$ So we don't have to assume
- $83\ 00:03:25.870 \longrightarrow 00:03:29.130$ that let's say body mass index has a normal distribution.
- $84\ 00:03:29.130 --> 00:03:31.980$ We literally don't have to specify distribution at all.
- $85\ 00{:}03{:}31.980 \dashrightarrow 00{:}03{:}34.540$ It's all about the random selection into the sample
- $86\ 00:03:34.540 \longrightarrow 00:03:35.850$ that lets us get our estimates
- $87\ 00:03:35.850$ --> 00:03:38.823 and be assured that we have unbiased estimates.
- $88\ 00:03:39.970 \longrightarrow 00:03:42.590$ So here's an example in case there are folks
- $89\ 00:03:42.590 --> 00:03:44.500$ out in the audience who don't have experience
- $90\ 00:03:44.500$ --> 00:03:47.600 with the sort of complex survey design or design features.
- 91 00:03:47.600 --> 00:03:49.240 So this is a really silly little example
- 92 $00:03:49.240 \longrightarrow 00:03:50.530$ of a stratified sample.
- 93 $00:03:50.530 \longrightarrow 00:03:52.540$ So here I have a population
- $94\ 00:03:52.540 \longrightarrow 00:03:54.730$ of two different types of animals.
- 95 00:03:54.730 --> 00:03:56.710 I have cats and I have dogs.
- 96 00:03:56.710 --> 00:04:00.023 And in this population I happen to have 12 cats and \$8.
- 97 $00:04:00.870 \longrightarrow 00:04:02.590$ And I have taken a sample.
- 98 00:04:02.590 --> 00:04:06.560 Stratified sample where I took two cats and two dogs.
- $99\ 00:04:06.560 \longrightarrow 00:04:08.890$ So in this design the selection probabilities

- 100 00:04:08.890 --> 00:04:10.890 are known for all of the units, right?
- $101\ 00:04:10.890 --> 00:04:13.980$ Because I know that there's a two out of eight chance
- 102 00:04:13.980 --> 00:04:16.150 I pick a dog and a two out of 12 chance
- 103 00:04:16.150 --> 00:04:18.440 that I pick a cat, right?
- $104\ 00:04:18.440 \longrightarrow 00:04:20.530$ So the probability a cat is selected is 1/6
- $105\ 00:04:20.530 \longrightarrow 00:04:23.300$ then the probability of dog is selected is 1/4.
- $106~00{:}04{:}23.300 \dashrightarrow 00{:}04{:}25.550$ Now, how do I estimate a proportion of interest?
- $107\ 00:04:25.550 --> 00:04:27.830$ Let's say it's the proportion of orange animals
- $108\ 00:04:27.830 \longrightarrow 00:04:28.730$ in the population.
- 109 00:04:28.730 --> 00:04:30.100 Like here in my sample,
- 110 00:04:30.100 --> 00:04:32.270 I have one of four orange animals,
- $111\ 00:04:32.270 \longrightarrow 00:04:34.390$ but if I chose that as my estimator
- 112 00:04:34.390 --> 00:04:37.180 I'd be ignoring the fact that I know how I selected
- $113\ 00:04:37.180 \longrightarrow 00:04:39.310$ these animals into my sample.
- $114\ 00:04:39.310 \longrightarrow 00:04:41.520$ So what we do is we wait the sample units
- $115\ 00:04:41.520 --> 00:04:43.930$ to produce design unbiased estimates, right?
- $116\ 00:04:43.930 \longrightarrow 00:04:47.580$ Because this one dog kinda counts
- 117 00:04:47.580 --> 00:04:49.570 differently than one cat, right?
- 118 00:04:49.570 --> 00:04:50.950 Because there were only eight dogs
- $119\ 00:04:50.950 \longrightarrow 00:04:53.600$ to begin with but there were 12 cats.
- $120\ 00{:}04{:}53.600 \dashrightarrow 00{:}04{:}56.590$ So if I want to estimate the proportion of orange animals
- $121\ 00:04:56.590 \longrightarrow 00:05:00.270$ I would say this cat is a weight is six
- $122\ 00:05:00.270 \longrightarrow 00:05:02.340$ because there's two of them and 12 total.
- $123\ 00:05:02.340 \longrightarrow 00:05:04.310$ So 12 divided by two is six.
- $124\ 00:05:04.310 \longrightarrow 00:05:06.280$ So there's six in the numerator.
- $125\ 00{:}05{:}06.280 \dashrightarrow 00{:}05{:}08.210$ And then the denominator is the sum of the weights
- 126 00:05:08.210 --> 00:05:09.570 of all the selected units,

- $127\ 00{:}05{:}09.570 \dashrightarrow 00{:}05{:}12.150$ the cats are each six and the dogs are each four.
- 128~00:05:12.150 --> 00:05:14.740 So I actually get my estimate a proportion of 30%.
- $129\ 00:05:14.740 \longrightarrow 00:05:16.550$ So instead of 25%.
- $130\ 00:05:16.550 \longrightarrow 00:05:17.920$ So that kind of weighted estimator
- $131\ 00:05:17.920 \longrightarrow 00:05:20.190$ is what we do in probability sampling.
- $132\ 00:05:20.190 --> 00:05:22.310$ And we don't have to say what the distribution
- $133\ 00:05:22.310 \longrightarrow 00:05:24.160$ of dogs or cats is in the sample
- $134\ 00:05:24.160 \longrightarrow 00:05:25.940$ or orangeness in the sample,
- $135\ 00:05:25.940 \longrightarrow 00:05:28.623$ we entirely rely on the selection mechanism.
- $136\ 00:05:29.870 \longrightarrow 00:05:32.200$ What ended up happening in the real world
- 137 00:05:32.200 --> 00:05:34.680 a lot of the time is we don't actually get to use
- $138\ 00:05:34.680 \longrightarrow 00:05:36.230$ those kinds of complex designs.
- $139\ 00:05:36.230 \longrightarrow 00:05:37.580$ And instead we collect data
- $140\ 00{:}05{:}37.580 \dashrightarrow 00{:}05{:}40.230$ through what's called a non-probability sample.
- 141 00:05:40.230 --> 00:05:42.150 So in a non-probability sample,
- $142\ 00:05:42.150 \longrightarrow 00:05:43.470$ it's pretty easy to define.
- $143\ 00{:}05{:}43.470 \dashrightarrow 00{:}05{:}46.040$ You cannot calculate the probability of selection
- $144\ 00:05:46.040 \longrightarrow 00:05:47.170$ into the sample, right?
- $145\ 00:05:47.170 -> 00:05:49.440$ So we simply don't know what the mechanism
- $146\ 00:05:49.440 --> 00:05:52.720$ was that made at unit enter our sample.
- $147\ 00:05:52.720 \dashrightarrow 00:05:55.020$ I know there's the biostatistics students in the audience,
- $148\ 00{:}05{:}55{.}020$ --> $00{:}05{:}57{.}290$ and you've all probably done a lot of data analysis.
- $149\ 00:05:57.290 --> 00:05:59.680$ And I would venture a guess that a lot of the times
- $150\ 00:05:59.680 --> 00:06:01.090$ your application datasets
- 151 00:06:01.090 --> 00:06:02.540 are non-probability samples, right?

- $152\ 00:06:02.540 \dashrightarrow 00:06:05.090$ A lot of the times there are convenience samples.
- $153\ 00:06:05.090 --> 00:06:06.960\ I$ work a lot with biomedical researchers
- $154\ 00:06:06.960 \longrightarrow 00:06:08.430$ studying cancer patients.
- $155\ 00{:}06{:}08.430 \dashrightarrow 00{:}06{:}11.580$ Well guess what, it's almost always a convenient sample
- 156 00:06:11.580 --> 00:06:12.850 of cancer patients, right?
- 157 00:06:12.850 --> 00:06:14.610 It's who will agree to be in the study?
- 158 00:06:14.610 --> 00:06:16.770 Who can I find to be in my study?
- $159\ 00:06:16.770 --> 00:06:18.610$ Other types of non-probability samples
- $160\ 00:06:18.610 \longrightarrow 00:06:21.950$ include things like voluntary or self-selection sampling,
- 161 00:06:21.950 --> 00:06:23.690 quota sampling, that's a really old,
- $162\ 00:06:23.690 \longrightarrow 00:06:27.850$ old school method from polling back many years ago.
- 163 00:06:27.850 --> 00:06:30.040 Judgment sampling or snowball sampling.
- $164\ 00:06:30.040 \longrightarrow 00:06:31.030$ So there's a lot of different ways
- $165~00{:}06{:}31.030 \dashrightarrow 00{:}06{:}33.053$ you can get non-probability samples.
- $166\ 00:06:34.040 \longrightarrow 00:06:36.800$ So if we go back to the dog and cat example,
- $167\ 00{:}06{:}36.800 \dashrightarrow 00{:}06{:}38.970$ if I didn't know anything about how these animals
- $168\ 00{:}06{:}38.970 \dashrightarrow 00{:}06{:}41.430$ got into my sample and I just saw the four of them,
- $169\ 00:06:41.430 \longrightarrow 00:06:43.210$ and one of them was orange,
- 170~00:06:43.210 --> 00:06:48.210 I guess, I'm gonna guess 25% of my population is orange.
- 171 00:06:48.290 --> 00:06:49.123 Right?
- $172\ 00:06:49.123 --> 00:06:50.290$ I don't have any other information
- 173 00:06:50.290 --> 00:06:52.500 I can't recreate the population
- 174 00:06:52.500 --> 00:06:54.090 like I could with the weighting.
- $175\ 00:06:54.090 --> 00:06:57.270$ Where I knew how many cats in the population
- $176\ 00:06:57.270 \longrightarrow 00:06:59.220$ did each of my sampled cats represent
- $177\ 00:06:59.220 \longrightarrow 00:07:00.790$ and similarly for the dogs.

 $178\ 00{:}07{:}00.790 \dashrightarrow 00{:}07{:}02.830$ So of course our best guess looking at these data

179 00:07:02.830 --> 00:07:04.610 would just be 25%, right?

 $180\ 00:07:04.610 \longrightarrow 00:07:07.350$ One out of the four animals is orange.

 $181\ 00:07:07.350 \longrightarrow 00:07:10.410$ So when you think about a non-probability sample,

182 00:07:10.410 --> 00:07:12.460 how much faith do you put in that estimate,

183 00:07:12.460 --> 00:07:13.403 that proportion?

184 00:07:14.640 --> 00:07:15.900 Hard to say, right?

 $185\ 00{:}07{:}15.900 \dashrightarrow 00{:}07{:}19.300$ It depends on what you believe about the population

 $186\ 00:07:19.300 \longrightarrow 00:07:22.530$ and how you selected this non-probability sample

 $187\ 00:07:22.530 \longrightarrow 00:07:25.620$ but you do not have the safety net of the probability sample

 $188\ 00:07:25.620 --> 00:07:27.840$ that guaranteed you're gonna get an unbiased estimate

189 00:07:27.840 --> 00:07:30.373 of repeated applications of the sampling.

 $190\ 00:07:31.810 \longrightarrow 00:07:34.200$ So I've already used the word selection bias

191 00:07:34.200 --> 00:07:36.920 a lot and sort of being assuming that, you know what I mean.

192 $00{:}07{:}36.920 \dashrightarrow 00{:}07{:}39.580$ So now I'm gonna come back to it and define it

193 00:07:39.580 --> 00:07:42.420 So selection bias is bias arising

194 00:07:42.420 --> 00:07:44.800 when part of the target population

195 00:07:44.800 --> 00:07:46.950 is not in the sample population, right?

 $196\ 00{:}07{:}46.950 {\:{\mbox{--}}}{>}\ 00{:}07{:}49.390$ So when there's a mismatch between who got into your sample

 $197\ 00:07:49.390 --> 00:07:51.250$ and who was supposed to get into your sample, right?

198 00:07:51.250 --> 00:07:52.830 Who's the population?

199 00:07:52.830 --> 00:07:55.910 Or in a more general statistical kind of way,

 $200\ 00{:}07{:}55.910 \dashrightarrow 00{:}07{:}59.050$ when some population units are sampled at a different rate

- $201\ 00:07:59.050 \longrightarrow 00:08:00.100$ than you meant.
- $202\ 00:08:00.100 --> 00:08:02.910$ It's lik you meant for there to be a certain selection
- 203 00:08:02.910 --> 00:08:05.840 probability for orange animals or for dogs
- $204\ 00:08:05.840 \longrightarrow 00:08:07.740$ but it didn't actually end up that way.
- $205\ 00:08:07.740 --> 00:08:10.610$ This will end up down the path of selection bias.
- $206\ 00{:}08{:}10.610 \dashrightarrow 00{:}08{:}13.090$ And I will note that again, as you are biostats students
- 207 00:08:13.090 --> 00:08:15.080 you've probably had some epidemiology.
- $208\ 00:08:15.080 --> 00:08:17.490$ And epidemiologists talk about selection bias as well.
- 209 00:08:17.490 --> 00:08:19.270 It's the same concept, right?
- $210\ 00{:}08{:}19.270 \dashrightarrow 00{:}08{:}21.810$ That concept of who is ending up in your sample.
- 211 $00:08:21.810 \longrightarrow 00:08:24.383$ And is there some sort of a bias in the mechanism?
- 212 00:08:25.610 --> 00:08:27.850 So selection bias is in fact the predominant
- $213\ 00:08:27.850 \longrightarrow 00:08:30.270$ concern with non-probability samples.
- 214 00:08:30.270 --> 00:08:32.410 In these non-probability samples,
- $215\ 00{:}08{:}32.410 \dashrightarrow 00{:}08{:}35.640$ the units in the sample might be really different
- $216\ 00:08:35.640 \longrightarrow 00:08:37.270$ from the units not in the sample,
- $217\ 00:08:37.270 \longrightarrow 00:08:39.570$ but we can't tell how different they are.
- $218\ 00{:}08{:}39.570 \dashrightarrow 00{:}08{:}42.970$ Whether we're talking about people, dogs, cats, hospitals,
- $219\ 00:08:42.970 \longrightarrow 00:08:44.220$ whatever we're talking about.
- $220\ 00{:}08{:}44.220$ --> $00{:}08{:}47.260$ However, these units got into my sample, I don't know.
- 221 00:08:47.260 --> 00:08:49.380 So I don't know if the people in my sample
- $222\ 00:08:49.380 \longrightarrow 00:08:52.610$ look like my population or not.
- 223 00:08:52.610 --> 00:08:54.560 And an important key thing to know
- $224\ 00:08:54.560 \longrightarrow 00:08:56.520$ is that probability samples
- $225\ 00:08:56.520 \longrightarrow 00:08:59.120$ when we have a low response rates, right?

- $226\ 00{:}08{:}59.120 \dashrightarrow 00{:}09{:}01.210$ So when there are a lot of people not responding
- 227 00:09:01.210 --> 00:09:02.770 you're basically ending up back
- 228 00:09:02.770 --> 00:09:04.730 at a non-probability sample, right?
- 229 00:09:04.730 --> 00:09:06.660 Where we have this beautiful design,
- $230\ 00:09:06.660 \longrightarrow 00:09:10.180$ we know everybody's sampling weight, we draw a sample,
- 231 00:09:10.180 --> 00:09:13.510 oops, ut then only 30% of people respond to my sample.
- $232\ 00{:}09{:}13.510 \dashrightarrow 00{:}09{:}16.050$ You're basically injecting that bias back in again.
- $233\ 00:09:16.050 \longrightarrow 00:09:19.673$ Sort of undoing the beauty of the probability sample.
- $234\ 00:09:20.920 \longrightarrow 00:09:22.780$ So when we think about a selection
- 235 00:09:22.780 --> 00:09:25.300 bias and selection into a sample,
- $236\ 00:09:25.300 \longrightarrow 00:09:27.570$ we can categorize them in two ways.
- 237 00:09:27.570 --> 00:09:30.400 And Dr. McDougal, actually,
- $238\ 00:09:30.400 \longrightarrow 00:09:32.100$ when he was giving you my brief little bio
- $239\ 00:09:32.100 \longrightarrow 00:09:34.350$ used the words that I'm sure you've used
- $240\ 00:09:34.350 \dashrightarrow 00:09:37.260$ in your classes before like ignorable and non-ignorable.
- 241 00:09:37.260 --> 00:09:39.410 These are usually are more commonly applied
- 242 00:09:39.410 --> 00:09:40.660 to missingness, right?
- 243 00:09:40.660 --> 00:09:42.560 So ignorable missingness mechanisms
- $244\ 00:09:42.560 \longrightarrow 00:09:45.210$ and non-ignorable missingness mechanisms.
- $245\ 00{:}09{:}45.210 \dashrightarrow 00{:}09{:}47.640$ Missing at random, missing completely at random
- 246 00:09:47.640 --> 00:09:49.900 or missing not at random, right?
- $247\ 00:09:49.900 \longrightarrow 00:09:51.720$ Same exact framework here.
- 248 00:09:51.720 --> 00:09:53.750 But instead of talking about missingness
- $249\ 00:09:53.750 \longrightarrow 00:09:56.390$ we're talking about selection into the sample.
- $250\ 00{:}09{:}56.390 \dashrightarrow 00{:}09{:}58.850$ So when we have an ignorable selection mechanism.

- $251\ 00:09:58.850 \longrightarrow 00:10:00.550$ that means the probability of selection
- $252\ 00{:}10{:}00.550 \dashrightarrow 00{:}10{:}01.977$ depends on things I observed.
- $253\ 00{:}10{:}01.977 \dashrightarrow 00{:}10{:}05.170$ Right, it depends on the observed characteristics.
- $254\ 00{:}10{:}05.170 \dashrightarrow 00{:}10{:}07.700$ When I have a non-negotiable selection mechanism
- $255\ 00:10:07.700 \longrightarrow 00:10:09.514$ now that probability of selection depends
- $256\ 00:10:09.514 \longrightarrow 00:10:11.820$ on observed characteristics.
- 257 00:10:11.820 --> 00:10:13.790 Again, this is not really a new concept
- $258~00:10:13.790 \dashrightarrow 00:10:15.310$ if you understanded about missing data,
- $259\ 00:10:15.310 --> 00:10:18.453$ just apply to selection into the sample.
- $260\ 00:10:19.670 \longrightarrow 00:10:21.560$ So in a probability sample
- $261\ 00{:}10{:}21.560 \dashrightarrow 00{:}10{:}24.060$ we might have different probabilities of selection
- 262~00:10:24.060 --> 00:10:27.760 for different types of units like for cats versus for dogs.
- 263 00:10:27.760 --> 00:10:30.670 But we know exactly how they differ, right?
- $264\ 00:10:30.670 --> 00:10:32.890$ It's because I designed my survey
- $265\ 00:10:32.890 \longrightarrow 00:10:35.720$ based on his characteristic of dog versus cat
- $266~00{:}10{:}35.720 \dashrightarrow 00{:}10{:}38.110$ and I know exactly the status of dog versus cat
- $267\ 00{:}10{:}38.110 \dashrightarrow 00{:}10{:}41.690$ for my entire population in order to do that selection.
- $268\ 00:10:41.690 --> 00:10:45.320$ So I absolutely can estimate the proportion of orange,
- $269\ 00{:}10{:}45.320 \dashrightarrow 00{:}10{:}49.390$ animals unbiasedly in the sense of taking repeated
- $270\ 00:10:49.390 --> 00:10:51.910$ stratified samples and estimating that proportion.
- 271 00:10:51.910 --> 00:10:54.360 I hadn't guaranteed that I'm gonna get an unbiased
- 272 00:10:54.360 --> 00:10:55.430 estimate, right?
- $273\ 00:10:55.430 \longrightarrow 00:10:57.300$ So this selection mechanism
- 274 00:10:57.300 --> 00:10:59.760 is definitely not non-ignorable, right?

- $275\ 00{:}10{:}59.760 \dashrightarrow 00{:}11{:}01.980$ This is definitely an ignorable selection mechanism
- 276 00:11:01.980 --> 00:11:03.540 in the sense that it only depends
- 277 00:11:03.540 --> 00:11:05.800 on observed characteristics.
- 278 00:11:05.800 --> 00:11:09.200 But if my four animals had just come from,
- 279 00:11:09.200 --> 00:11:10.033 I don't know where?
- $280\ 00:11:10.033 \longrightarrow 00:11:11.030$ Convenience.
- 281 00:11:11.030 --> 00:11:13.830 Well now why did they end up in my sample?
- $282\ 00:11:13.830 \longrightarrow 00:11:16.110$ It could depend on something that we didn't observe.
- 283 00:11:16.110 --> 00:11:17.670 What breed of dog it was?
- $284\ 00:11:17.670 \longrightarrow 00:11:20.080$ The age of the dog, the color of the dog.
- $285\ 00:11:20.080 --> 00:11:22.340$ It could have been pretty much anything, right?
- $286\ 00{:}11{:}22.340 \dashrightarrow 00{:}11{:}24.180$ That's the problem with the convenient sample.
- 287 00:11:24.180 --> 00:11:25.410 You don't know why those units
- $288\ 00:11:25.410 --> 00:11:28.303$ often self-selected to be into your sample.
- 289 00:11:29.350 --> 00:11:32.050 So now I'm gonna head into the kind of ugly statistical
- $290\ 00:11:32.050 \longrightarrow 00:11:34.750$ notation portion of this stock.
- $291\ 00:11:34.750 \longrightarrow 00:11:36.720$ So we'll start with estimated proportions.
- 292 00:11:36.720 --> 00:11:40.658 So we'll use Y as our binary indicator
- $293\ 00:11:40.658 \longrightarrow 00:11:42.860$ for the outcome, okay?
- $294\ 00:11:42.860 \longrightarrow 00:11:45.310$ But here I'm gonna talk about Y
- $295\ 00:11:45.310 --> 00:11:48.670$ more generally as all the survey data.
- $296\ 00:11:48.670 \longrightarrow 00:11:50.110$ So we'll start with Y as all the survey data,
- $297\ 00:11:50.110 --> 00:11:51.210$ then we're gonna narrow it down to Y
- 298 00:11:51.210 --> 00:11:52.940 as the binary indicator?
- $299~00{:}11{:}52.940 \dashrightarrow 00{:}11{:}56.740$ So we can partition our survey data into the data
- $300\ 00:11:56.740 \longrightarrow 00:11:58.197$ for the units we got in the sample

- $301\ 00:11:58.197 \longrightarrow 00:12:01.020$ and the data for units that are not in the sample.
- $302\ 00:12:01.020 \longrightarrow 00:12:02.700\ I$ so selected into the sample versus
- $303\ 00:12:02.700 \longrightarrow 00:12:04.640$ not selected into the sample.
- $304\ 00:12:04.640 \longrightarrow 00:12:07.180$ But for everybody I have Z,
- $305\ 00:12:07.180 \longrightarrow 00:12:08.740$ I have some fully observed
- $306\ 00:12:08.740 \longrightarrow 00:12:11.310$ what are often called design variables.
- $307~00{:}12{:}11.310 \dashrightarrow 00{:}12{:}13.960$ So this is where we are using information
- $308\ 00:12:13.960 --> 00:12:16.140$ that we know about an entire population
- $309\ 00:12:16.140 --> 00:12:19.520$ to select our sample in the world of probability sampling.
- $310\ 00:12:19.520 --> 00:12:21.653$ And then S is the selection indicator.
- $311\ 00:12:22.520 --> 00:12:25.840$ So these three variables have a joint distribution.
- 312 00:12:25.840 --> 00:12:27.070 And most of the time,
- $313\ 00:12:27.070 \longrightarrow 00:12:29.940$ what we care about is Y given Z.
- 314 00:12:29.940 --> 00:12:31.950 Right, we're interested in estimating
- $315\ 00:12:31.950 --> 00:12:34.120$ some outcome characteristic
- $316\ 00{:}12{:}34.120$ --> $00{:}12{:}36.890$ conditional on some other characteristic, right?
- $317\ 00:12:36.890 --> 00:12:40.360$ Average weight for dogs, average weight for cats, right?
- $318\ 00:12:40.360 \longrightarrow 00:12:42.010\ Y$ given Z.
- 319 00:12:42.010 --> 00:12:45.440 But Y given Z is only part of the issue,
- $320\ 00:12:45.440 --> 00:12:47.750$ there's also a selection mechanism, right?
- $321\ 00:12:47.750 \longrightarrow 00:12:49.120$ So there's also this function
- 322 00:12:49.120 --> 00:12:53.320 of how do you predict selection S with Y and Z.
- $323\ 00:12:53.320 --> 00:12:56.210$ And I'm using this additional Greek letter psi here
- $324\ 00:12:56.210 \longrightarrow 00:12:58.230$ to denote additional variables
- 325 00:12:58.230 --> 00:12:59.830 that might be involved, right?

- 326 00:12:59.830 --> 00:13:02.540 'Cause selection could depend on more than just Y and Z.
- 327 00:13:02.540 --> 00:13:04.230 It could depend on something outside
- $328\ 00:13:04.230 \longrightarrow 00:13:05.593$ of that set of variables.
- 329 00:13:06.670 --> 00:13:08.230 So when we have probability sampling,
- $330\ 00:13:08.230 \longrightarrow 00:13:09.140$ we have what's called
- 331 00:13:09.140 --> 00:13:12.270 an extremely ignorable selection mechanism,
- $332\ 00:13:12.270 --> 00:13:14.320$ which means selection can depend on Z,
- $333\ 00:13:14.320 \longrightarrow 00:13:16.440$ like when we stratified on animal type
- $334\ 00:13:16.440 \longrightarrow 00:13:18.470$ but it cannot depend on Y.
- 335 00:13:18.470 --> 00:13:21.960 Either the selected units Y or the excluded units Y
- $336\ 00:13:21.960 \longrightarrow 00:13:23.830$ doesn't depend on either.
- $337\ 00:13:23.830 --> 00:13:27.340$ Kind of vaguely like the MCAR of selection mechanisms.
- $338\ 00:13:27.340 \longrightarrow 00:13:29.340$ It doesn't depend on Y at all.
- $339\ 00:13:29.340 \longrightarrow 00:13:30.520$ Observed or unobserved.
- $340\ 00:13:30.520 \longrightarrow 00:13:31.460$ But it can depend on Z.
- $341\ 00:13:31.460 \longrightarrow 00:13:33.680$ So that makes it different than MCAR.
- $342\ 00:13:33.680 \longrightarrow 00:13:35.800$ So including a unit into the sample
- 343 00:13:35.800 --> 00:13:38.930 is independent of those survey outcomes Y
- 344 00:13:38.930 --> 00:13:41.110 and also any unobserved variables, right?
- 345 00:13:41.110 --> 00:13:43.720 That phi here, that phi goes away.
- $346\ 00:13:43.720 \longrightarrow 00:13:46.310$ So selection only depends on Z.
- $347\ 00:13:46.310 \longrightarrow 00:13:49.170$ So if I'm interested in this inference target
- 348~00:13:49.170 --> 00:13:51.490 I can ignore the selection mechanism.
- $349\ 00:13:51.490 \longrightarrow 00:13:54.060$ So this is kind of parallels that idea
- $350~00{:}13{:}54.060 \dashrightarrow 00{:}13{:}56.320$ in the missingness, in the missing data literature, right?
- $351\ 00:13:56.320 \longrightarrow 00:13:58.520$ If I have an ignorable missingness mechanism
- $352\ 00:13:58.520 \longrightarrow 00:14:00.350$ I can ignore that part of it.
- 353 00:14:00.350 --> 00:14:01.870 I don't have to worry about modeling

- $354\ 00:14:01.870 \longrightarrow 00:14:03.870$ the probability that a unit is selected.
- $355\ 00{:}14{:}05.010 \dashrightarrow 00{:}14{:}08.230$ But the bad news in our non-probability sampling,
- 356 00:14:08.230 --> 00:14:10.610 very, very arguably true
- $357\ 00{:}14{:}10.610 \dashrightarrow 00{:}14{:}13.010$ that you could have non ignorable selection, right?
- $358\ 00:14:13.010 --> 00:14:16.030$ It's easy to make an argument for why the people
- 359 00:14:16.030 --> 00:14:17.500 who ended up into your sample,
- $360\ 00{:}14{:}17.500 \dashrightarrow 00{:}14{:}20.210$ your convenient sample are different than the people
- $361\ 00:14:20.210 \longrightarrow 00:14:22.130$ who don't enter your sample.
- $362\ 00:14:22.130 \longrightarrow 00:14:24.030$ Think about some of these big data examples.
- $363\ 00:14:24.030 \longrightarrow 00:14:25.610$ Think about Twitter data.
- $364\ 00:14:25.610 \longrightarrow 00:14:26.840$ Well, I mean, you know,
- 365 00:14:26.840 --> 00:14:28.730 the people who use Twitter are different
- 366 00:14:28.730 --> 00:14:30.720 than the people who don't use Twitter, right?
- $367\ 00:14:30.720 \longrightarrow 00:14:32.400$ In lots of different ways.
- $368\ 00:14:32.400 \longrightarrow 00:14:33.670$ So if you're going to think about drawing
- $369\ 00:14:33.670 -> 00:14:35.940$ some kind of inference about the population,
- $370\ 00:14:35.940 --> 00:14:39.100$ you can't just ignore that selection mechanism.
- $371\ 00:14:39.100 --> 00:14:40.770$ You need to think about how do they enter
- 372 00:14:40.770 --> 00:14:42.210 into your Twitter sample
- $373\ 00{:}14{:}42.210 \dashrightarrow 00{:}14{:}44.150$ and how might they be different than the people
- $374\ 00:14:44.150 --> 00:14:47.040$ who did not enter into your Twitter sample.
- $375\ 00{:}14{:}47.040 \dashrightarrow 00{:}14{:}49.280$ So when we're thinking about the selection mechanism
- 376 00:14:49.280 --> 00:14:50.860 basically nothing goes away, right?
- $377\ 00:14:50.860 \longrightarrow 00:14:53.297$ We can't ignore this selection mechanism.
- $378\ 00:14:53.297 --> 00:14:54.570$ But we have to think
- 379 00:14:54.570 --> 00:14:55.930 about it when we want to make inference,

- 380 00:14:55.930 --> 00:14:58.590 even when our inference is about Y given Z, right?
- $381\ 00:14:58.590 \longrightarrow 00:14:59.900$ Even when we don't actually care
- $382\ 00:14:59.900 \longrightarrow 00:15:01.970$ about the selection mechanism.
- $383\ 00:15:01.970 \longrightarrow 00:15:03.970$ So the problem with probability samples
- $384\ 00:15:03.970 \longrightarrow 00:15:07.350$ is that it's often very, very hard to model S
- $385\ 00:15:07.350 --> 00:15:09.790$ or we don't really have a good set of data
- 386 00:15:09.790 --> 00:15:11.290 with which to model the probability
- $387\ 00:15:11.290 --> 00:15:13.500$ someone ended up in your sample.
- $388\ 00{:}15{:}13.500 \dashrightarrow 00{:}15{:}17.050$ And that's basically what you have to do to generalize
- $389\ 00:15:17.050 \longrightarrow 00:15:18.690$ to the population, right?
- $390\ 00:15:18.690 --> 00:15:21.370$ There's methods that exist for non-probability samples
- 391 00:15:21.370 --> 00:15:23.790 require you to do something along the lines
- $392\ 00:15:23.790 \longrightarrow 00:15:25.750$ of finding another dataset
- $393\ 00:15:25.750 --> 00:15:27.190$ that has similar characteristics
- $394\ 00{:}15{:}27.190 \dashrightarrow 00{:}15{:}29.860$ and model the probability of being in the probability
- 395 00:15:29.860 --> 00:15:31.090 sample, right?
- $396\ 00:15:31.090 \longrightarrow 00:15:33.540$ So that's doable in many situations
- $397\ 00:15:33.540 --> 00:15:35.490$ but what we're looking for is a method
- 398 00:15:35.490 --> 00:15:37.040 that doesn't require you to do that
- $399\ 00:15:37.040 \longrightarrow 00:15:40.030$ but instead says, let's do a sensitivity analysis.
- 400 00:15:40.030 --> 00:15:43.140 Let's say, how big of a problem
- $401\ 00:15:43.140 --> 00:15:46.100$ might selection bias be if we ignored
- 402 00:15:46.100 --> 00:15:47.250 the selection mechanism, right?
- $403\ 00:15:47.250 \longrightarrow 00:15:49.240$ If we just sort of took our sample on faith
- $404\ 00:15:49.240 \longrightarrow 00:15:51.970$ as if it were an SRS from the population.
- $405\ 00:15:51.970 \longrightarrow 00:15:53.530$ How wrong would we be
- $406\ 00:15:53.530 --> 00:15:57.173$ depending on how bad our selection bias problem is?

- $407\ 00:15:58.570 \longrightarrow 00:16:00.220$ So there has been previous work done
- $408\ 00:16:00.220 \longrightarrow 00:16:03.140$ in this area, in surveys often.
- 409 00:16:03.140 --> 00:16:05.560 Try to think about how confident
- $410\ 00:16:05.560 --> 00:16:07.890$ are we that we can generalize to the population
- $411\ 00:16:07.890 \longrightarrow 00:16:10.320$ even when we're doing a probability sample.
- $412\ 00{:}16{:}10.320 \dashrightarrow 00{:}16{:}13.620$ So there's work on thinking about the representativeness
- $413\ 00:16:13.620 \longrightarrow 00:16:14.510$ of a sample.
- $414\ 00:16:14.510 \longrightarrow 00:16:18.290$ So that's again, the generalizability to the population.
- 415 00:16:18.290 --> 00:16:20.710 So there's something called an R-indicator,
- $416\ 00:16:20.710 \longrightarrow 00:16:24.870$ which is a function of response probabilities
- $417\ 00:16:24.870 \longrightarrow 00:16:25.980$ or propensities,
- $418\ 00:16:25.980 --> 00:16:27.870$ but it doesn't involve the survey variables.
- $419\ 00{:}16{:}27.870 \dashrightarrow 00{:}16{:}31.810$ So it's literally comparing the probability of response
- 420 00:16:31.810 --> 00:16:34.330 to a survey for different demographic,
- 421 00:16:34.330 --> 00:16:36.850 across different demographic characteristics, for example.
- 422 00:16:36.850 --> 00:16:37.683 Right.
- $423\ 00:16:37.683 \longrightarrow 00:16:40.030$ And seeing who is more likely to respond then who else?
- 424 00:16:40.030 --> 00:16:41.470 And if there are those differences
- $425\ 00:16:41.470 \longrightarrow 00:16:43.143$ then adjustments need to be made.
- 426 00:16:44.180 --> 00:16:46.500 There's also something called the H1 indicator,
- 427 00:16:46.500 --> 00:16:49.430 which does bring Y into the equation
- $428\ 00{:}16{:}49.430 \dashrightarrow 00{:}16{:}51.910$ but it assumes ignorable selection.
- $429\ 00:16:51.910 \longrightarrow 00:16:53.600$ So it's going to assume that the Y
- $430\ 00:16:53.600 \longrightarrow 00:16:55.583$ excluded gets dropped out.
- $431\ 00:16:57.690 --> 00:16:59.470$ The selection mechanism is only depends
- $432\ 00{:}16{:}59.470 \dashrightarrow 00{:}17{:}02.830$ on things that you observe, so you can ignore it, right?
- $433\ 00:17:02.830 \longrightarrow 00:17:04.490$ So it's ignorable.

- $434\ 00:17:04.490 \longrightarrow 00:17:05.820$ So that's not what we're interested in.
- $435\ 00{:}17{:}05.820 \dashrightarrow 00{:}17{:}08.870$ 'Cause we're really worried in the non probability space
- $436\ 00:17:08.870 \longrightarrow 00:17:11.603$ that we can't ignore the selection mechanism.
- $437\ 00:17:12.670 \longrightarrow 00:17:14.840$ And there isn't relatively new indicator
- $438\ 00:17:14.840 --> 00:17:17.773$ called that they called the SMUB, S-M-U-B.
- $439\ 00:17:18.710 \longrightarrow 00:17:21.140$ That is an index that actually extends
- $440\ 00:17:21.140 \longrightarrow 00:17:22.840$ this idea of selection bias
- $441\ 00:17:22.840 \longrightarrow 00:17:25.410$ to allow for non ignorable selection.
- $442\ 00{:}17{:}25.410 --> 00{:}17{:}28.760$ So it lets you say, well, what would my point estimate
- $443\ 00{:}17{:}28.760 \dashrightarrow 00{:}17{:}32.880$ be for a mean if selection were in fact ignorable,
- $444\ 00{:}17{:}32.880 --> 00{:}17{:}34.500$ and now let's go to the other extreme,
- $445\ 00:17:34.500 \longrightarrow 00:17:37.080$ suppose selection only depends on Y.
- 446 00:17:37.080 --> 00:17:39.050 And I'm trying to estimate average weight
- $447\ 00:17:39.050 \longrightarrow 00:17:40.490$ and whether or not you entered my sample
- 448 00:17:40.490 --> 00:17:42.740 is entirely dependent on your weight.
- $449\ 00:17:42.740 \longrightarrow 00:17:44.680$ That's really not ignorable.
- $450\ 00{:}17{:}44.680 \dashrightarrow 00{:}17{:}47.080$ And then it kind a bounds the potential magnitude
- $451\ 00:17:47.080 \longrightarrow 00:17:48.083$ for the problem.
- 452 00:17:48.930 --> 00:17:51.870 So that SMUB, this estimator is really close
- $453\ 00:17:51.870 \longrightarrow 00:17:54.720$ to what we want but we want it for proportions.
- $454\ 00:17:54.720$ --> 00:17:59.720 especially because in survey work and in large datasets.
- $455\ 00:18:00.390 \longrightarrow 00:18:02.630$ we very often have categorical data
- 456 00:18:02.630 --> 00:18:05.160 or very, very often binary data.
- 457 00:18:05.160 --> 00:18:06.860 If you think about if you've ever participated
- $458\ 00{:}18{:}06.860 \dashrightarrow 00{:}18{:}09.710$ in an online survey or filled out those kinds of things
- 459 00:18:09.710 --> 00:18:11.230 very often, right, You're checking a box.

- $460\ 00:18:11.230 \longrightarrow 00:18:13.200$ It's multiple choice, select all that apply.
- $461\ 00:18:13.200 --> 00:18:16.540$ It's lots and lots of binary data floating around out there.
- $462\ 00:18:16.540 --> 00:18:19.200$ And I'll show you a couple of examples.
- 463 00:18:19.200 --> 00:18:21.780 So that was a lot of kind of me talking
- $464\ 00:18:21.780 \longrightarrow 00:18:23.460$ at you about the framework.
- $465\ 00:18:23.460 --> 00:18:27.250$ Now, let me bring this down to a solid example application.
- $466\ 00:18:27.250 \longrightarrow 00:18:29.650$ So I'm going to use the national survey
- $467~00{:}18{:}29.650 \dashrightarrow 00{:}18{:}32.370$ of family growth as a fake population.
- $468~00{:}18{:}32.370 \dashrightarrow 00{:}18{:}35.600$ So I want you to pretend that I have a population
- 469 00:18:35.600 --> 00:18:37.880 of 19,800 people, right?
- $470\ 00{:}18{:}37.880 \to 00{:}18{:}40.440$ It happens to be that I pulled it from the national survey
- 471 00:18:40.440 --> 00:18:41.273 of family growth,
- $472\ 00{:}18{:}41.273 \dashrightarrow 00{:}18{:}43.150$ that's not really important that that was the source.
- $473\ 00:18:43.150 --> 00:18:46.310$ I've got this population of about 20,000 people.
- 474 00:18:46.310 --> 00:18:48.240 But let's pretend we're doing a study
- $475\ 00:18:48.240 \longrightarrow 00:18:49.890$ and I was only able to select
- $476\ 00:18:49.890 \longrightarrow 00:18:51.890$ into my sample smartphone users.
- $477\ 00:18:51.890 \longrightarrow 00:18:54.430$ Because I did some kind of a survey that was on their,
- 478 00:18:54.430 --> 00:18:55.750 you had to take it on your phone.
- $479\ 00:18:55.750 \longrightarrow 00:18:57.170$ So if you did not have a smartphone
- $480\ 00:18:57.170 \longrightarrow 00:19:00.050$ you could not be selected into my sample.
- 481 00:19:00.050 --> 00:19:02.740 In this particular case, in this fake population,
- 482 00:19:02.740 --> 00:19:04.490 it's a very high selection fraction.
- 483 00:19:04.490 --> 00:19:07.260 So about 80% of my population is in my sample.
- 484 00:19:07.260 --> 00:19:10.620 That in and of itself is very unusual, right?

- 485 00:19:10.620 --> 00:19:12.540 A non-probability sample is usually very,
- $486\ 00:19:12.540 --> 00:19:15.370$ very small compared to the full population
- 487 00:19:15.370 --> 00:19:16.580 let's say of the United States
- 488 00:19:16.580 --> 00:19:18.220 if that's who we're trying to generalize to.
- 489 00:19:18.220 --> 00:19:19.640 But for the purposes of illustration
- $490\ 00:19:19.640 --> 00:19:22.330$ it helps to have a pretty high selection fraction.
- $491\ 00{:}19{:}22.330 \dashrightarrow 00{:}19{:}24.280$ And we'll assume that the outcome we're interested
- $492\ 00:19:24.280$ --> 00:19:27.930 in is whether or not the individual has ever been married.
- 493 00:19:27.930 --> 00:19:29.390 So this is person level data, right?
- 494 00:19:29.390 --> 00:19:30.600 Ever been married.
- 495 00:19:30.600 --> 00:19:32.410 And it is...
- $496\ 00:19:32.410 \longrightarrow 00:19:33.980$ we wanna estimate it by gender,
- $497\ 00:19:33.980 \longrightarrow 00:19:36.400$ and I will note that the NSFG only calculate
- $498\ 00:19:36.400 --> 00:19:39.000$ or only captures gender as a binary variable.
- $499\ 00:19:39.000 \longrightarrow 00:19:40.930$ This is a very long standing survey,
- 500 00:19:40.930 --> 00:19:42.430 been going on since the seventies.
- $501~00{:}19{:}42.430 \to 00{:}19{:}44.800$ We know our understanding of gender as a construct
- 502 00:19:44.800 --> 00:19:46.590 has grown a lot since the seventies
- $503\ 00:19:46.590 \longrightarrow 00:19:48.320$ but this survey, and in fact
- $504\ 00:19:48.320 \longrightarrow 00:19:50.840$ many governmental surveys still treat gender
- 505 00:19:50.840 --> 00:19:51.930 as a binary variable.
- $506\ 00:19:51.930 --> 00:19:53.840$ So that's our limitation here
- $507\ 00:19:53.840 --> 00:19:56.330$ but I just want to acknowledge that.
- 508 00:19:56.330 --> 00:19:57.980 So in this particular case,
- 509 00:19:57.980 --> 00:19:59.960 we know the true selection bias, right?
- 510 00:19:59.960 --> 00:20:03.580 Because I actually have all roughly 20,000 people
- 511~00:20:03.580 --> 00:20:05.990 so that therefore I can calculate what's the truth.

- $512\ 00:20:05.990 --> 00:20:08.287$ and then I can use my smartphone sample and say,
- 513 00:20:08.287 --> 00:20:10.630 "Well, how much bias is there?"
- 514 00:20:10.630 --> 00:20:12.930 So it turns out that in the full sample
- $515\ 00:20:12.930 \longrightarrow 00:20:16.320\ 46.8\%$ of the females have never been married.
- $516~00{:}20{:}16.320 \dashrightarrow 00{:}20{:}19.830$ And 56.6% of the males had never been married.
- 517 00:20:19.830 --> 00:20:22.890 But if I use my selected sample of smartphone users
- $518\ 00:20:22.890 \longrightarrow 00:20:24.880$ I'm getting a, well, very close,
- $519\ 00:20:24.880 \longrightarrow 00:20:27.710$ but slightly smaller estimate for females.
- $520\ 00:20:27.710 \longrightarrow 00:20:30.170\ 46.6\%$ never married.
- 521 00:20:30.170 --> 00:20:31.990 And for males it's like about a percentage
- $522\ 00:20:31.990 \longrightarrow 00:20:35.290$ point lower than the truth, 55.5%.
- $523\ 00:20:35.290 --> 00:20:37.610$ So not a huge amount of bias here.
- $524~00{:}20{:}37.610 \dashrightarrow 00{:}20{:}41.070$ My smartphone users are not all that non-representative
- $525\ 00:20:41.070 --> 00:20:42.920$ with respect to the entire sample,
- 526 00:20:42.920 --> 00:20:44.390 at least with respect to whether
- 527 00:20:44.390 --> 00:20:46.810 or not they've ever been married.
- $528\ 00:20:46.810 --> 00:20:48.670$ So when we have binary data,
- $529~00{:}20{:}48.670 \dashrightarrow 00{:}20{:}52.790$ an important point of reference is what happens if we assume
- $530\ 00:20:52.790 \longrightarrow 00:20:55.410$ everybody not in my sample is a one, right?
- $531~00{:}20{:}55.410 \dashrightarrow 00{:}20{:}58.030$ What if every body not in my sample was never married
- 532 00:20:58.030 --> 00:21:00.660 or everyone not in my sample
- 533 00:21:00.660 --> 00:21:02.730 is a no to never married, right?
- 534 00:21:02.730 --> 00:21:05.260 So like has, has ever been married?
- $535\ 00{:}21{:}05.260$ --> $00{:}21{:}07.410$ And these are what's called the Manski bounds.
- $536\ 00:21:07.410 \longrightarrow 00:21:10.140$ When you fill in all zeros or fill in old bonds
- $537\ 00:21:10.140 --> 00:21:12.167$ for the missing values or the values

- $538\ 00:21:12.167 \longrightarrow 00:21:14.080$ for those non-selected folks.
- $539\ 00:21:14.080 \longrightarrow 00:21:15.490$ So we can bound the bias.
- $540\ 00:21:15.490 \longrightarrow 00:21:20.490$ So the bias of this estimate of 46.6 or 46.6%
- $541\ 00:21:20.770 \longrightarrow 00:21:22.680$ has to be by definition
- $542\ 00:21:22.680 \longrightarrow 00:21:25.910$ between negative 0.098 and positive 0.085.
- $543\ 00:21:25.910 \longrightarrow 00:21:28.850$ Because those are the two ends of putting all zeros
- $544\ 00:21:28.850 \longrightarrow 00:21:32.090$ or all ones for the people who are not in my sample.
- 545 00:21:32.090 --> 00:21:34.610 So this is unlike a continuous variable, right?
- $546\ 00:21:34.610 \longrightarrow 00:21:37.810$ Where we can't actually put a finite bound on the bias.
- 547 00:21:37.810 --> 00:21:39.670 We can with a proportion, right?
- 548 00:21:39.670 --> 00:21:42.140 So this is why, for example,
- $549~00{:}21{:}42.140 \dashrightarrow 00{:}21{:}45.010$ if any of you ever work on smoking cessation studies
- $550\ 00:21:45.010 --> 00:21:46.850$ often they do sensitivity analysis.
- $551~00{:}21{:}46.850 \dashrightarrow 00{:}21{:}49.710$ People who drop out assume they're all smoking, right?
- 552 00:21:49.710 --> 00:21:51.400 Or assume they're all not smoking.
- 553 00:21:51.400 --> 00:21:53.180 They're not calling it that
- $554~00{:}21{:}53.180 \longrightarrow 00{:}21{:}56.240$ but they're getting the Manski bounds.
- 555 00:21:56.240 --> 00:21:57.200 Okay.
- $556\ 00:21:57.200 \longrightarrow 00:22:00.080$ So the question is, can we do better than the Manski bounds?
- $557\ 00:22:00.080 \longrightarrow 00:22:02.360$ Because these are actually pretty wide bounds,
- 558 00:22:02.360 --> 00:22:04.100 relative to the size of the true bias,
- $559\ 00:22:04.100 \longrightarrow 00:22:06.170$ and these are very wide.
- 560~00:22:06.170 --> 00:22:10.190 And imagine a survey where we didn't have 80% selected.
- $561\ 00:22:10.190 \longrightarrow 00:22:11.870$ What if we had 10% selected?
- $562~00{:}22{:}11.870 \dashrightarrow 00{:}22{:}13.990$ Well, then the Manski bounds are gonna be useless, right?

- 563 00:22:13.990 --> 00:22:15.670 plug in, all zeros plug in all ones,
- 564 00:22:15.670 --> 00:22:17.420 you're gonna get these insane estimates
- $565\ 00:22:17.420 \longrightarrow 00:22:19.620$ that are nowhere close to what you observed.
- 566 00:22:20.800 --> 00:22:22.920 So going back to the statistical notation,
- $567\ 00:22:22.920 \longrightarrow 00:22:24.400$ this is where I said we're going to use Y
- 568 00:22:24.400 --> 00:22:25.550 in a slightly different way.
- $569\ 00:22:25.550 \longrightarrow 00:22:30.070$ Now, Y, and now forward is the binary variable of interest.
- 570 00:22:30.070 --> 00:22:32.680 So in this case, in this NSFG example
- 571 00:22:32.680 --> 00:22:34.003 it was never married.
- $572\ 00{:}22{:}34.900 \dashrightarrow 00{:}22{:}38.490$ We have a bunch of auxiliary variables that we observed
- 573 00:22:38.490 --> 00:22:41.180 for everybody in the selected sample;
- 574 00:22:41.180 --> 00:22:43.310 age, race, education, et cetera,
- $575\ 00:22:43.310 \longrightarrow 00:22:44.843$ and I'm gonna call those Z.
- $576~00:22:47.560 \longrightarrow 00:22:50.640$ Assume also that we have summary statistics
- $577\ 00:22:50.640 \longrightarrow 00:22:52.950$ on Z for the selected cases.
- 578 00:22:52.950 --> 00:22:55.460 So I don't observe Z for everybody, right?
- 579 00:22:55.460 --> 00:22:56.950 All my non-smartphone users,
- $580~00:22:56.950 \longrightarrow 00:22:59.670~I~don't~know~for~each~one~of~them,~what~is~their~gender?$
- $581\ 00:22:59.670 \longrightarrow 00:23:01.650$ What is their age? What is their race?
- 582 00:23:01.650 --> 00:23:03.310 But I don't actually observe that.
- 583 00:23:03.310 --> 00:23:05.610 But I observed some kinda summary statistic.
- $584~00{:}23{:}05.610 \dashrightarrow 00{:}23{:}09.150$ But a mean vector and a covariance matrix of Z.
- $585~00{:}23{:}09.150 \dashrightarrow 00{:}23{:}12.240$ So I have some source of what does my population
- 586 00:23:12.240 --> 00:23:14.300 look like at an aggregate level?
- $587~00{:}23{:}14.300 \dashrightarrow 00{:}23{:}16.120$ And in practice, this would come from something
- $588~00{:}23{:}16.120 \dashrightarrow 00{:}23{:}19.510$ like census data or in a very large probability sample,

- $589\ 00:23:19.510 \longrightarrow 00:23:21.020$ something where we would be pretty confident
- $590\ 00:23:21.020 \longrightarrow 00:23:23.440$ This is reflective of the population.
- 591~00:23:23.440 --> 00:23:27.000 Will note that if we have data for the population
- 592 00:23:27.000 --> 00:23:28.510 and not the non-selected,
- 593 00:23:28.510 --> 00:23:30.180 then we can kind do subtraction, right?
- $594\ 00:23:30.180 --> 00:23:32.460$ We can take the data for the population
- $595\ 00:23:32.460 --> 00:23:34.630$ and aggregate and go backwards
- $596~00{:}23{:}34.630 \dashrightarrow 00{:}23{:}36.320$ to figure out what it would be for the non-selected
- $597\ 00:23:36.320 \longrightarrow 00:23:40.090$ by effectively backing out the selected cases.
- 598 00:23:40.090 --> 00:23:41.590 And similarly another problem
- $599\ 00:23:41.590 \longrightarrow 00:23:42.530$ is that we don't have the variance.
- $600\ 00:23:42.530 \longrightarrow 00:23:44.040$ We could just assume it's what we observe
- $601\ 00:23:44.040 \longrightarrow 00:23:45.140$ in the selected cases.
- $602\ 00:23:46.450 --> 00:23:48.490$ So how are we gonna use this in order
- $603\ 00:23:48.490 \longrightarrow 00:23:52.410$ to estimate of selection bias,
- $604\ 00:23:52.410 \longrightarrow 00:23:53.243$ what we're gonna come up
- $605\ 00{:}23{:}53.243 \dashrightarrow 00{:}23{:}56.210$ with this measure of unadjusted bias for proportions
- $606\ 00:23:56.210 \longrightarrow 00:23:57.823$ called the MUBP.
- $607\ 00:23:58.760 --> 00:24:01.940$ So the MUBP is an extension of the SMUB
- $608\ 00:24:01.940 \longrightarrow 00:24:04.470$ that was for means, for continuous variables
- 609 00:24:04.470 --> 00:24:06.030 to binary outcomes, right?
- $610\ 00:24:06.030 \longrightarrow 00:24:07.470$ To proportions.
- $611\ 00{:}24{:}07.470 --> 00{:}24{:}10.380$ High-level, it's based on pattern-mixture models.
- 612 00:24:10.380 --> 00:24:12.700 It requires you to make explicit assumptions
- $613\ 00:24:12.700 \longrightarrow 00:24:15.470$ about the distribution of the selection mechanism,
- 614 00:24:15.470 --> 00:24:17.730 and it provides you a sensitivity analysis,
- $615\ 00:24:17.730 \longrightarrow 00:24:20.010$ basically make different assumptions on S,

- 616 00:24:20.010 --> 00:24:21.910 I don't know what that distribution is,
- 617 00:24:21.910 --> 00:24:24.240 and you're gonna get a range of bias.
- 618 00:24:24.240 --> 00:24:27.950 So that's that idea of how wrong might we be?
- 619 00:24:27.950 --> 00:24:29.990 So we're trying to just tighten those bounds
- $620\ 00:24:29.990 \longrightarrow 00:24:30.910$ compared to the Manski bounce.
- $621\ 00{:}24{:}30.910 \dashrightarrow 00{:}24{:}33.480$ Where we don't wanna have to rely on plug in all zeros,
- $622\ 00:24:33.480 \longrightarrow 00:24:34.550$ plug in all ones,
- 623 00:24:34.550 --> 00:24:35.750 we wanna shrink that interval
- $624\ 00{:}24{:}35.750 \dashrightarrow 00{:}24{:}38.420$ to give us something a little bit more meaningful.
- $625\ 00:24:38.420 \longrightarrow 00:24:40.910$ So the basic idea behind how this works
- $626\ 00{:}24{:}40.910 \dashrightarrow 00{:}24{:}44.160$ before I show you the formulas is we can measure
- 627 00:24:44.160 --> 00:24:47.480 the degree of selection bias in Z, right?
- 628 00:24:47.480 --> 00:24:50.390 Because we observed Z for our selected sample,
- $629\ 00{:}24{:}50.390 \dashrightarrow 00{:}24{:}53.170$ and we observed at an aggregate for the population.
- $630\ 00:24:53.170 \longrightarrow 00:24:56.370$ So I can see, for example, that if in my selected sample,
- 631~00:24:56.370 --> 00:25:00.970 I have 55% females but in the population it's 50% females.
- $632\ 00:25:00.970 \longrightarrow 00:25:02.590$ Well, I can see that bias.
- 633 00:25:02.590 --> 00:25:04.330 Right, I can do that comparison.
- 634 00:25:04.330 --> 00:25:08.360 So absolutely I can tell you how much selection bias
- $635\ 00:25:08.360 \longrightarrow 00:25:11.380$ there is for all of my auxiliary variables.
- 636 00:25:11.380 --> 00:25:15.670 So if my outcome Y is related to my Zs
- 637 00:25:15.670 --> 00:25:18.550 then knowing something about the selection bias in Z
- 638 00:25:18.550 --> 00:25:21.970 tells me something about the selection bias in Y.

- 639 00:25:21.970 --> 00:25:24.700 It doesn't tell me exactly the selection bias in ${\bf Y}$
- $640\ 00:25:24.700 \longrightarrow 00:25:28.380$ but it gives me some information in the selection bias in Y.
- $641\ 00:25:28.380 \longrightarrow 00:25:31.850$ So in the extreme imagine if your Zs
- $642\ 00:25:31.850 \longrightarrow 00:25:33.340$ in your selected sample
- $643\ 00{:}25{:}33.340 \dashrightarrow 00{:}25{:}36.210$ in aggregate looked exactly like the population.
- 644 00:25:36.210 --> 00:25:39.600 Well, then you'd be pretty confident, right?
- $645~00{:}25{:}39.600 \dashrightarrow 00{:}25{:}41.850$ That there's not an enormous amount of selection bias
- $646\ 00:25:41.850 \longrightarrow 00:25:44.623$ in Y assuming that Y was related to the Z.
- $647\ 00:25:46.290 --> 00:25:48.020$ So we're gonna use pattern-mixture models
- $648~00{:}25{:}48.020 \dashrightarrow 00{:}25{:}51.770$ to explicitly model that distribution of S, right?
- $649\ 00:25:51.770 --> 00:25:53.960$ And we're especially gonna focus on the case
- $650\ 00:25:53.960 \longrightarrow 00:25:55.930$ when selection depends on Y.
- 651 00:25:55.930 --> 00:25:59.483 It depends on our binary outcome of interest.
- 652 00:26:00.320 --> 00:26:02.880 So again, Y is that binary variable interest,
- $653\ 00:26:02.880 \longrightarrow 00:26:05.380$ we only have it for the selected sample.
- $654~00{:}26{:}05.380 \dashrightarrow 00{:}26{:}08.420$ In the NSFG example it's whether the woman or man
- $655\ 00:26:08.420 \longrightarrow 00:26:09.740$ has ever been married.
- $656\ 00{:}26{:}09.740 --> 00{:}26{:}12.970$ We have Z variables available for the selected cases
- $657\ 00{:}26{:}12.970 \dashrightarrow 00{:}26{:}16.280$ in micro data and an aggregate for the non-selected sample,
- 658 00:26:16.280 --> 00:26:17.590 a demographic characteristics
- $659\ 00:26:17.590 \longrightarrow 00:26:20.713$ like age, education, marital status, et cetera.
- 660 00:26:21.740 --> 00:26:23.610 And the way that we're gonna go
- 661 00:26:23.610 --> 00:26:24.920 about doing this is we're gonna try
- 662 00:26:24.920 --> 00:26:27.230 to get back to the idea of normality,
- $663~00{:}26{:}27.230 \longrightarrow 00{:}26{:}30.330$ because then as you all know, when everything's normal

- 664 00:26:30.330 --> 00:26:31.680 it's great, right?
- $665\ 00:26:31.680 -> 00:26:34.210$ It's easy to work with the normal distribution.
- $666\ 00{:}26{:}34.210 \dashrightarrow 00{:}26{:}36.720$ So the way we can do that with a binary variable
- $667\ 00:26:36.720 \longrightarrow 00:26:39.330$ is we can think about latent variables.
- 668~00:26:39.330 --> 00:26:42.150 So we're going to think about a latent variable called U.
- $669\ 00{:}26{:}42.150 \dashrightarrow 00{:}26{:}44.840$ That is an underlying, unobserved latent variables.
- $670\ 00{:}26{:}44.840 \to 00{:}26{:}48.040$ So unobserved for every body, including our selected sample.
- 671 00:26:48.040 --> 00:26:49.950 And it's basically thresholded.
- $672\ 00{:}26{:}49.950 \dashrightarrow 00{:}26{:}54.460$ And when U crosses zero, well, then Y goes from zero to one.
- $673\ 00:26:54.460 \longrightarrow 00:26:57.940$ So I'm sure many, all of you have seen probit regression,
- $674\ 00:26:57.940 \longrightarrow 00:26:59.250$ or this is what happens
- 675 00:26:59.250 --> 00:27:01.360 and this is how probit regression is justified,
- $676\ 00:27:01.360 \longrightarrow 00:27:02.583$ via latent variables.
- $677\ 00:27:03.540 \longrightarrow 00:27:05.920$ So we're going to take our Zs
- $678\ 00:27:05.920 \longrightarrow 00:27:08.220$ that we have for the selected cases,
- $679\ 00:27:08.220 \longrightarrow 00:27:11.030$ and essentially reduce the dimensionality.
- 680 00:27:11.030 --> 00:27:12.680 We're gonna take the Zs,
- $681~00{:}27{:}12.680 \dashrightarrow 00{:}27{:}17.080$ run a probate regression of Y on Z in the selected cases,
- $682\ 00:27:17.080 \longrightarrow 00:27:18.890$ and pull out the linear predictor
- $683\ 00:27:18.890 \longrightarrow 00:27:20.320$ from the regression, right?
- $684\ 00:27:20.320 \longrightarrow 00:27:22.430$ The X beta, right?
- 685 00:27:22.430 --> 00:27:24.050 Sorry, Z beta.
- $686\ 00:27:24.050 \longrightarrow 00:27:25.460$ And I'm gonna call that X.
- 687 00:27:25.460 --> 00:27:29.580 That is my proxy for Y or my Y hat, right?
- $688~00{:}27{:}29.580 \dashrightarrow 00{:}27{:}31.560$ It's just the predicted value from the regression.

- $689\ 00:27:31.560 \longrightarrow 00:27:34.660$ And I can get that for every single observation
- 690 00:27:34.660 --> 00:27:36.770 in my selected sample, of course, right?
- $691\ 00:27:36.770 --> 00:27:39.120$ Just plug in each individual's Z values
- $692\ 00:27:39.120 \longrightarrow 00:27:40.390$ and get out their Y hat.
- 693 00:27:40.390 --> 00:27:42.240 That's my proxy value.
- $694\ 00:27:42.240 \longrightarrow 00:27:43.540$ And it's called the proxy
- 695 00:27:43.540 --> 00:27:45.060 because it's the prediction, right?
- 696 00:27:45.060 --> 00:27:46.820 It's our sort of best guess at Y
- $697\ 00:27:46.820 \longrightarrow 00:27:47.903$ based on this model.
- 698~00:27:48.760 --> 00:27:52.000 So I can get it for every observation in my selected sample,
- 699 00:27:52.000 --> 00:27:55.720 but very importantly I can also get it on average
- $700\ 00:27:55.720 \longrightarrow 00:27:57.480$ for the non-selective sample.
- $701\ 00:27:57.480 \longrightarrow 00:28:01.130$ So I have all my beta hats for my probit regression,
- $702\ 00:28:01.130 --> 00:28:03.050$ and I'm gonna plug in Z-bar.
- 703~00:28:03.050 --> 00:28:05.880 And I'm going to plug in the average value of my Zs.
- $704\ 00:28:05.880 --> 00:28:08.160$ And that's going to give me the average value
- $705\ 00:28:08.160 \longrightarrow 00:28:10.890$ of X for the non-selected cases.
- $706\ 00:28:10.890 --> 00:28:12.930\ I\ don't\ have an actual observed value$
- 707 00:28:12.930 --> 00:28:14.580 for all those non-selective cases
- 708 00:28:14.580 --> 00:28:16.390 but I have the average, right?
- 709 00:28:16.390 --> 00:28:19.240 So I could think about comparing the average Z value
- $710~00:28:19.240 \longrightarrow 00:28:22.170$ in the aggregate, in the non-selected cases
- 711 00:28:22.170 --> 00:28:24.180 to that average Z among my selected cases.
- $712\ 00:28:24.180 \longrightarrow 00:28:25.540$ And that is of course
- 713 00:28:25.540 --> 00:28:27.890 exactly where we're gonna get those index from.
- 714 00:28:28.970 --> 00:28:31.100 So I have my selection indicator S,
- $715\ 00:28:31.100 \longrightarrow 00:28:33.000$ so in the smartphone example,

716 00:28:33.000 --> 00:28:35.080 that's S equals one for the smartphone users

717 00:28:35.080 --> 00:28:37.230 and S equals zero for the non-smartphone users

 $718\ 00:28:37.230 \longrightarrow 00:28:38.670$ who weren't in my sample.

719 00:28:38.670 --> 00:28:40.150 And importantly, I'm going to allow

 $720\ 00:28:40.150 \longrightarrow 00:28:42.750$ there to be some other covariates V

721 00:28:42.750 --> 00:28:46.010 floating around in here that are independent of Y and X

 $722\ 00:28:46.010 \longrightarrow 00:28:48.220$ but could be related to selection.

723 00:28:48.220 --> 00:28:49.113 Okay.

 $724\ 00:28:49.113 \longrightarrow 00:28:51.110$ So it could be related to how you got into my sample

725 00:28:51.110 --> 00:28:53.310 but importantly, not related to the outcome.

726 00:28:54.870 --> 00:28:58.550 So diving into the math here, the equations,

727 00:28:58.550 --> 00:29:01.890 we're gonna assume a proxy pattern-mixture model for U,

728 00:29:01.890 --> 00:29:04.510 the latent variable underlying Y

729 00:29:04.510 --> 00:29:07.883 and X given the selection indicator.

730 00:29:07.883 --> 00:29:11.110 So what a pattern-mixture model does is it says

731 00:29:11.110 --> 00:29:13.530 there's a totally separate distribution

 $732\ 00:29:13.530 --> 00:29:16.400$ or joint distribution of Y and X for the selected units

 $733\ 00:29:16.400 \longrightarrow 00:29:17.770$ and the non-selected units.

 $734\ 00:29:17.770 \longrightarrow 00:29:21.010$ Notice that all my mus, all my sigmas, my rho,

 $735\ 00:29:21.010 --> 00:29:23.420$ they've all got a superscript of j, right?

736 00:29:23.420 --> 00:29:26.810 So that's whether your S equals zero or S equals one.

737 00:29:26.810 --> 00:29:31.240 So two totally different bi-variate normal distributions

738 $00:29:31.240 \longrightarrow 00:29:32.690$ before Y and X,

 $739\ 00:29:32.690 \longrightarrow 00:29:35.000$ depending on if you're selected or non-selected.

 $740\ 00:29:35.000 --> 00:29:36.650$ And then we have a marginal distribution

- $741\ 00:29:36.650 \longrightarrow 00:29:39.123$ just Bernoulli, for the selection indicator.
- $742\ 00:29:40.070 \longrightarrow 00:29:43.367$ However, I'm sure you all immediately are thinking,
- 743 00:29:43.367 --> 00:29:44.627 "Well, that's great,
- 744 00:29:44.627 --> 00:29:47.187 "but I don't have any information to estimate
- 745~00:29:47.187 --> 00:29:50.830 "some of these parameters for the non-selected cases."
- 746 00:29:50.830 --> 00:29:52.970 Clearly, for the selected cases, right?
- 747 00:29:52.970 --> 00:29:53.803 S equals one.
- $748\ 00:29:53.803 \longrightarrow 00:29:55.220\ I$ can estimate all of these things.
- 749 00:29:55.220 --> 00:29:58.480 But I can't estimate them for the non-selected sample
- 750 00:29:58.480 --> 00:30:00.520 because I might observe X-bar
- 751 00:30:00.520 --> 00:30:03.100 but I don't observe anything having to do with you.
- 752 00:30:03.100 --> 00:30:05.660 'Cause I have no Y information.
- $753\ 00:30:05.660 \longrightarrow 00:30:07.500$ So in order to identify this model
- $754\ 00:30:07.500 \longrightarrow 00:30:08.870$ and be able to come up with estimates
- $755\ 00:30:08.870 \longrightarrow 00:30:10.210$ for all of these parameters,
- $756\ 00:30:10.210$ --> 00:30:13.460 we have to make an assumption about the selection mechanism.
- $757\ 00:30:13.460 --> 00:30:16.070$ So we assume that the probability of selection
- $758\ 00:30:16.070 \longrightarrow 00:30:19.070$ into my sample is a function of U.
- $759\ 00:30:19.070 --> 00:30:20.690$ So we're allowing it to be not ignorable.
- 760 00:30:20.690 --> 00:30:23.170 Remember that's underlying Y and X,
- 761 00:30:23.170 --> 00:30:25.450 that proxy which is a function of Z.
- $762~00{:}30{:}25.450 \dashrightarrow 00{:}30{:}29.520$ So that's observed and V, those other variables.
- 763 00:30:29.520 --> 00:30:30.940 And in particular, we're assuming
- $764~00{:}30{:}30{.}940 \dashrightarrow 00{:}30{:}33{.}910$ that it's this funny looking form of combination
- 765 00:30:33.910 --> 00:30:35.150 of X and U.

- 766 00:30:35.150 --> 00:30:38.490 That depends on this sensitivity parameter phi.
- $767\ 00:30:38.490 \longrightarrow 00:30:41.010$ So phi it's one minus phi times X
- $768\ 00:30:41.010 \longrightarrow 00:30:42.790$ and phi times U.
- 769 00:30:42.790 --> 00:30:44.640 So that's essentially weighting
- $770\ 00:30:44.640 --> 00:30:46.780$ the contributions of those two pieces.
- 771 00:30:46.780 --> 00:30:48.750 How much of selection is dependent
- 772 00:30:48.750 --> 00:30:50.330 on the thing that I observe
- $773\ 00:30:50.330 \longrightarrow 00:30:52.860$ or the proxy builds off the auxiliary variables
- 774 00:30:52.860 --> 00:30:56.120 and how much of it is depending on the underlying latent U
- $775\ 00:30:56.120 \longrightarrow 00:30:57.020$ related to Y,
- $776\ 00:30:57.020 \longrightarrow 00:30:58.360$ that is definitely not observed
- $777\ 00:30:58.360 \longrightarrow 00:30:59.680$ for the non-selected.
- 778 00:30:59.680 --> 00:31:00.513 Okay.
- 779 00:31:00.513 --> 00:31:01.650 And there's a little X star here,
- $780\ 00:31:01.650 \longrightarrow 00:31:03.170$ that's sort of a technical detail.
- 781 00:31:03.170 --> 00:31:04.800 We're rescaling the proxy.
- $782\ 00:31:04.800 \longrightarrow 00:31:07.070$ So it has the same variance as U,
- 783 $00:31:07.070 \longrightarrow 00:31:08.920$ very unimportant mathematical detail.
- $784\ 00:31:10.090 --> 00:31:13.110$ So we have this joint distribution
- $785\ 00:31:13.110 --> 00:31:15.570$ that is conditional on selection status.
- 78600:31:15.570 --> 00:31:18.860 And in addition to, we need that one assumption
- $787\ 00:31:18.860 \longrightarrow 00:31:19.693$ to identify things.
- $788\ 00:31:19.693 \longrightarrow 00:31:21.840$ We also have the latent variable problem.
- 789 00:31:21.840 --> 00:31:24.430 So latent variables do not have separately identifiable
- 790 00:31:24.430 --> 00:31:26.160 mean and variance, right?
- 791 00:31:26.160 --> 00:31:27.040 So that's just...
- 792 00:31:27.040 --> 00:31:28.649 Outside of the scope of this talk
- 793 00:31:28.649 --> 00:31:29.690 that's just a fact, right?

- $794\ 00:31:29.690 \longrightarrow 00:31:31.020$ So without loss of generality
- 795~00:31:31.020 --> 00:31:33.620 we're gonna set the variance of the latent variable
- $796\ 00:31:33.620 \longrightarrow 00:31:35.350$ for the select a sample equal to one.
- $797\ 00:31:35.350 --> 00:31:38.230$ So it's just the scale of the latent variable.
- $798~00{:}31{:}38.230 \dashrightarrow 00{:}31{:}42.210$ So what we actually care about is a function of you, right?
- 799 00:31:42.210 --> 00:31:44.590 It's the probability Y equals one marginally
- $800\ 00:31:44.590 \longrightarrow 00:31:46.400$ in my entire population.
- 801 00:31:46.400 --> 00:31:47.910 And so the probability Y equals one,
- $802\ 00:31:47.910 \longrightarrow 00:31:49.930$ is a probability U is greater than zero.
- $803\ 00:31:49.930 \longrightarrow 00:31:51.340$ That's that relationship.
- $804~00{:}31{:}51.340 \dashrightarrow 00{:}31{:}54.910$ And so it's a weighted average of the proportion
- $805\ 00:31:54.910 \longrightarrow 00:31:56.180$ in the selected sample
- $806\ 00{:}31{:}56.180 {\:\raisebox{---}{\text{---}}}> 00{:}31{:}59.870$ and the proportion in the non-selected sample, right?
- $807\ 00:31:59.870 \longrightarrow 00:32:00.703$ These are just...
- 808 00:32:00.703 --> 00:32:02.480 If U has this normal distribution
- $809\ 00:32:02.480 \longrightarrow 00:32:03.900$ this is how we get down to the probability
- 810 00:32:03.900 --> 00:32:04.900 U equals zero.
- $811\ 00:32:04.900 \longrightarrow 00:32:06.523$ Like those are those two pieces.
- $812\ 00:32:07.570 \longrightarrow 00:32:09.780$ So the key parameter that governs
- 813 00:32:09.780 --> 00:32:13.750 how this MUBP works is a correlation, right?
- 814 00:32:13.750 --> 00:32:16.810 It's the strength of the relationship between Y
- $815\ 00:32:16.810 \longrightarrow 00:32:18.280$ and your covariates.
- 816 00:32:18.280 --> 00:32:22.170 How good of a model do you have for Y, right?
- 817 00:32:22.170 --> 00:32:24.080 So remember we think back to that example
- 818 00:32:24.080 --> 00:32:26.440 of what if I had no biases Z.
- 819 00:32:26.440 --> 00:32:28.440 Or if Y wasn't related to Z,
- 820 00:32:28.440 --> 00:32:31.720 well, then who cares that there is no bias in Z.

- $821\ 00:32:31.720 --> 00:32:34.260$ But we want there to be a strong relationship
- 822 00:32:34.260 --> 00:32:38.973 between Z and Y so that we can kind of infer from Z to Y.
- 823 00:32:39.820 --> 00:32:42.560 So that correlation in this latent variable framework
- 824 00:32:42.560 --> 00:32:45.750 is called the biserial correlation of the binary X
- $825\ 00:32:45.750 \longrightarrow 00:32:46.920$ and the continuous.
- 826 00:32:46.920 --> 00:32:49.839 I mean, sorry, the binary Y and the continuous X, right?
- 827 00:32:49.839 --> 00:32:52.650 There's lots of different flavors of correlation,
- $828\ 00:32:52.650 \longrightarrow 00:32:54.890$ biserial is the name for this one
- 829 00:32:54.890 --> 00:32:57.330 that's a binary Y and a continuous X
- 830 00:32:57.330 --> 00:33:00.130 when we're thinking about the latent variable framework.
- 831 00:33:00.130 --> 00:33:01.470 Importantly, you can estimate
- $832\ 00:33:01.470 \longrightarrow 00:33:03.560$ this in the selected sample, right?
- 833 00:33:03.560 --> 00:33:06.200 So I can estimate the correlation between you and X
- $834\ 00:33:06.200 \longrightarrow 00:33:07.450$ among the selected sample.
- $835\ 00:33:07.450 \longrightarrow 00:33:08.800\ I\ can't$ for the non-selected sample,
- $836\ 00:33:08.800 \longrightarrow 00:33:11.700$ of course, but I can for the selected sample.
- $837\ 00:33:11.700 --> 00:33:14.070$ So the non-identifiable parameters
- $838\ 00:33:14.070 \longrightarrow 00:33:15.483$ of that pattern-mixture model, here they are.
- 839 00:33:15.483 --> 00:33:17.170 Like the mean for the latent variable,
- $840\ 00:33:17.170 \longrightarrow 00:33:18.570$ the variance for the latent variable
- $841\ 00{:}33{:}18.570 \dashrightarrow 00{:}33{:}21.740$ and that correlation for the non-selected sample
- $842\ 00{:}33{:}21.740 {\:{\mbox{--}}\!>}\ 00{:}33{:}24.130$ are in fact identified when we make this assumption
- $843\ 00:33:24.130 \longrightarrow 00:33:26.330$ on the selection mechanism.
- $844\ 00:33:26.330 \longrightarrow 00:33:30.070$ So let's think about some concrete scenarios.
- $845\ 00:33:30.070 \longrightarrow 00:33:32.050$ What if phi was zero?

- $846\ 00:33:32.050 \longrightarrow 00:33:33.110$ If phi is zero,
- $847\ 00:33:33.110 \longrightarrow 00:33:35.340$ we look up here at this part of the formula,
- $848\ 00:33:35.340 \longrightarrow 00:33:37.610$ well, then phi drops out it.
- 849 00:33:37.610 --> 00:33:40.300 So therefore selection only depends on X
- $850\ 00{:}33{:}40.300 \dashrightarrow 00{:}33{:}43.200$ and those extra variables V that don't really matter
- 851 00:33:43.200 --> 00:33:45.690 because V isn't related to X or Y.
- $852\ 00:33:45.690$ --> 00:33:49.700 This is an ignorable selection mechanism, okav.
- $853\ 00:33:49.700 \longrightarrow 00:33:51.510$ If on the other hand phi is one,
- $854\ 00:33:51.510 \longrightarrow 00:33:53.500$ well, then it entirely depends on U.
- 855 00:33:53.500 --> 00:33:55.070 X doesn't matter at all.
- $856\ 00{:}33{:}55.070 \dashrightarrow 00{:}33{:}57.590$ This is your worst, worst, worst case scenario, right?
- $857\ 00{:}33{:}57.590 \dashrightarrow 00{:}34{:}00.090$ Where whether or not you're in my sample only depends
- $858\ 00:34:00.090$ --> 00:34:03.817 on U and therefore only depends on the value of Y.
- $859\ 00:34:03.817 --> 00:34:06.797$ And so this is extremely not ignorable selection.
- 860 00:34:06.797 --> 00:34:09.510 And of course the truth is likely to lie
- 861 00:34:09.510 --> 00:34:11.210 somewhere in between, right?
- $862\ 00:34:11.210 --> 00:34:13.040$ Some sort of non-ignorable mechanism,
- $863\ 00:34:13.040 \longrightarrow 00:34:15.960$ a phi between zero and one, so that U matters
- $864\ 00:34:15.960 \longrightarrow 00:34:17.790$ but it's not the only thing that matters.
- $865\ 00:34:17.790 \longrightarrow 00:34:19.890$ Right, that X matters as well.
- 866 00:34:19.890 --> 00:34:20.723 Okay.
- 867 00:34:20.723 --> 00:34:22.250 So this is a kind of moderate,
- $868\ 00:34:22.250 \longrightarrow 00:34:23.410$ non-ignorable selection.
- 869 00:34:23.410 --> 00:34:26.070 That's most likely the closest to reality
- $870\ 00:34:26.070 --> 00:34:28.263$ with these non-probability samples.
- 871 00:34:30.120 --> 00:34:32.520 So for a specified value of phi.

- $872\ 00{:}34{:}32.520 \dashrightarrow 00{:}34{:}34.610$ So we pick a value for our sensitivity parameter.
- $873\ 00:34:34.610 --> 00:34:36.230$ There's no information in the data about it.
- 874 00:34:36.230 --> 00:34:40.340 We just pick it and we can actually estimate the mean of Y
- $875\ 00{:}34{:}40.340 \dashrightarrow 00{:}34{:}43.250$ and compare that to the selected sample proportion.
- 876 00:34:43.250 --> 00:34:45.100 So we take this select a sample proportion,
- 877 00:34:45.100 --> 00:34:47.480 subtract what we get as the truth
- $878\ 00:34:47.480 \longrightarrow 00:34:49.540$ for that particular value of phi,
- 879 00:34:49.540 --> 00:34:51.610 and that's our measure of bias, right?
- 880 00:34:51.610 --> 00:34:54.110 So this second piece that's being subtracted
- $881\ 00:34:54.110 \longrightarrow 00:34:54.943$ here depends on phi.
- $882\ 00:34:54.943 --> 00:34:56.850$ Right, it depends on what your value
- 883 00:34:56.850 --> 00:34:58.040 of your selected parameter is,
- $884\ 00:34:58.040 \longrightarrow 00:35:00.860$ or selection for your sensitivity parameter is.
- 885 00:35:00.860 --> 00:35:03.270 So in a nutshell, pick a selection mechanism
- 886 00:35:03.270 --> 00:35:05.500 by specifying specifying phi,
- 887 00:35:05.500 --> 00:35:07.270 estimate the overall proportion,
- 888 $00:35:07.270 \longrightarrow 00:35:10.057$ and then subtract to get your measure of bias.
- $889\ 00{:}35{:}10.057 \dashrightarrow 00{:}35{:}12.060$ And again, we don't know whether we're getting
- 890 00:35:12.060 --> 00:35:13.730 the right answer because it's depending
- $891\ 00:35:13.730 \longrightarrow 00:35:15.170$ on the sensitivity parameter
- 892 00:35:15.170 --> 00:35:18.670 but it's at least going to allow us to bound the problem.
- $893\ 00:35:18.670 \longrightarrow 00:35:20.750$ So the formula is quite messy,
- $894\ 00:35:20.750 \longrightarrow 00:35:24.020$ but it gives some insight into how this index works.
- $895\ 00:35:24.020 --> 00:35:26.660$ So this measure of bias is the selected sample
- 896 00:35:26.660 --> 00:35:29.450 mean minus that estimator, right?
- $897\ 00:35:29.450 \longrightarrow 00:35:31.760$ This is the overall mean of Y
- $898\ 00:35:31.760 \longrightarrow 00:35:33.910$ based on those latent variables.

- $899\ 00:35:33.910 \longrightarrow 00:35:35.560$ And what gets plugged in here
- $900\ 00:35:35.560 \longrightarrow 00:35:36.750$ importantly for the mean
- $901\ 00:35:36.750 \longrightarrow 00:35:39.030$ and the variance for the non-selected cases
- $902\ 00:35:39.030 \longrightarrow 00:35:42.030$ depends on a component that I've got colored blue here,
- $903\ 00:35:42.030 \longrightarrow 00:35:44.490$ and a component that I've got color red.
- $904\ 00:35:44.490 \longrightarrow 00:35:46.090$ So if we look at the red piece
- $905\ 00:35:46.090 \dashrightarrow 00:35:48.930$ this is the comparison of the proxy mean for the unselected
- $906\ 00:35:48.930 \longrightarrow 00:35:50.450$ and the selected cases.
- $907\ 00:35:50.450 \longrightarrow 00:35:52.310$ This is that bias in Z.
- $908\ 00:35:52.310 \longrightarrow 00:35:54.120$ The selection bias in Z,
- $909\ 00:35:54.120 \longrightarrow 00:35:55.340$ and it's just been standardized
- 910 00:35:55.340 --> 00:35:56.940 by its estimated variance, right?
- 911 00:35:56.940 --> 00:35:58.790 So that's how much selection bias
- 912 00:35:58.790 --> 00:36:01.510 was present in Z via X, right.
- 913 00:36:01.510 --> 00:36:04.800 Via using it to predict in the appropriate regression.
- 914 00:36:04.800 \rightarrow 00:36:07.850 Similarly, down here, how different is the variance
- 915 00:36:07.850 \rightarrow 00:36:10.400 of the selected and unselected cases for X.
- 916 00:36:10.400 --> 00:36:12.960 How much bias, selection bias is there in estimating
- 917 00:36:12.960 --> 00:36:14.160 the variance?
- 918 00:36:14.160 --> 00:36:16.270 So we're going to use that difference
- 919 00:36:16.270 --> 00:36:18.563 and scale the observed mean, right?
- 920 00:36:18.563 --> 00:36:21.530 There's that observed the estimated mean of U
- 921 00:36:21.530 --> 00:36:24.360 in the selected sample and how much it's gonna shift
- $922\ 00:36:24.360 \longrightarrow 00:36:26.430$ by is it depends on the selection,
- 923 00:36:26.430 --> 00:36:28.770 I mean, the sensitivity parameter phi,
- $924\ 00:36:28.770 --> 00:36:30.810$ and also that by serial correlation.

- 925 00:36:30.810 --> 00:36:33.920 So this is why the by serial correlation is so important.
- $926\ 00:36:33.920 \longrightarrow 00:36:36.810$ It is gonna dominate how much of the bias
- $927\ 00:36:36.810 \longrightarrow 00:36:39.543$ in X we're going to transfer over into Y.
- 928 00:36:41.700 --> 00:36:44.090 So if phi were zero,
- $929\ 00:36:44.090 \longrightarrow 00:36:45.470$ so if we wanna assume
- 930 00:36:45.470 --> 00:36:47.690 that it is an ignorable selection mechanism,
- 931 $00:36:47.690 \longrightarrow 00:36:49.520$ then this thing in blue here,
- $932\ 00:36:49.520 --> 00:36:52.300$ think about plugging zero here, zero here, zero everywhere,
- $933\ 00:36:52.300 \longrightarrow 00:36:54.500$ is just gonna reduce down to that correlation.
- $934\ 00:36:54.500 \longrightarrow 00:36:56.460$ So we're gonna shift the mean of U
- 935 00:36:56.460 --> 00:36:58.900 for the non-selective cases
- 936 00:36:58.900 --> 00:37:03.020 based on the correlation times that difference in X.
- 937 00:37:03.020 --> 00:37:05.880 Whereas if we have phi equals one,
- 938 00:37:05.880 --> 00:37:09.403 this thing in blue turns into one over the correlation.
- $939\ 00:37:10.350 \longrightarrow 00:37:12.070$ So here is where thinking about the magnitude
- $940\ 00:37:12.070 \longrightarrow 00:37:13.330$ of the correlation helps.
- 941 00:37:13.330 --> 00:37:15.227 If the correlation is really big, right?
- 942 00:37:15.227 --> 00:37:17.270 If the correlation is 0.8, 0.9,
- 943 00:37:17.270 --> 00:37:19.850 something really large than phi and...
- 944 00:37:19.850 --> 00:37:22.060 I mean, sorry, then rho and one over rho
- 945 00:37:22.060 --> 00:37:23.423 are very close, right?
- 946 00:37:23.423 --> 00:37:25.940 0.8 and 1/0.8 are pretty close.
- 947 00:37:25.940 --> 00:37:28.710 So if we're thinking about bounding this between phi
- 948 00:37:28.710 --> 00:37:30.160 equals zero and equals one,
- $949\ 00:37:30.160 --> 00:37:32.580$ our interval is gonna be relatively small.
- $950\ 00:37:32.580 \longrightarrow 00:37:34.620$ But if the correlation is small,
- 951 00:37:34.620 --> 00:37:37.200 the correlation were 0.2, oh, oh, right?

- $952\ 00:37:37.200 --> 00:37:38.700$ We're gonna get a really big interval
- 953 00:37:38.700 --> 00:37:40.100 because that correlation,
- 954 00:37:40.100 --> 00:37:42.770 we're gonna shift with the factor of multiplied by $0.2\,$
- $955\ 00:37:42.770 \longrightarrow 00:37:44.260$ but then one over 0.2.
- 956 00:37:44.260 --> 00:37:46.200 That's gonna be a really big shift
- $957\ 00:37:46.200 \longrightarrow 00:37:48.200$ in that mean of the latent variable U
- 958 $00:37:48.200 \longrightarrow 00:37:49.843$ and therefore the mean of Y.
- 959 00:37:51.290 --> 00:37:52.760 So how do we get these estimates?
- 960 00:37:52.760 --> 00:37:54.900 We have two possibilities. We can use what we call
- 961 $00:37:54.900 \longrightarrow 00:37:57.540$ modified maximum likelihood estimation.
- 962 00:37:57.540 --> 00:37:58.373 It's not true.
- 963 $00:37:58.373 \longrightarrow 00:38:00.080$ Maximum likelihood because we estimate
- $964\ 00:38:00.080 \longrightarrow 00:38:01.960$ the biserial correlation with something
- 965 00:38:01.960 --> 00:38:03.840 called a two step method, right?
- $966\ 00:38:03.840 \longrightarrow 00:38:07.180$ So instead of doing a full, maximum likelihood,
- 967 00:38:07.180 --> 00:38:11.590 we kind of take this cheat in which we set that mean of X
- $968\ 00:38:11.590 --> 00:38:14.520$ for the selected cases equal to what we observe,
- 969 00:38:14.520 --> 00:38:16.070 And then conditional not to estimate
- 970 00:38:16.070 --> 00:38:17.800 the by serial correlation.
- 971 00:38:17.800 --> 00:38:18.670 Yeah.
- 972 00:38:18.670 --> 00:38:21.920 And as a sensitivity analysis we would plug in zero one
- $973\ 00:38:21.920 \longrightarrow 00:38:23.410$ and maybe 0.5 in the middle
- $974\ 00:38:23.410 \longrightarrow 00:38:25.313$ as the values sensitivity parameter.
- $975\ 00:38:26.160 \longrightarrow 00:38:28.840$ Alternatively, and we feel is a much more attractive
- 976 00:38:28.840 --> 00:38:30.810 approach is to be Bayesian about this.
- 977 00:38:30.810 --> 00:38:34.120 So in this MML estimation,
- 978 00:38:34.120 --> 00:38:37.560 we are implicitly assuming that we know the betas

- $979\ 00:38:37.560 \longrightarrow 00:38:38.680$ from that probate regression.
- 980 00:38:38.680 --> 00:38:42.480 That we're essentially treating X like we know it.
- 981 00:38:42.480 --> 00:38:43.770 But we don't know X, right?
- 982 00:38:43.770 --> 00:38:44.820 That probate regression,
- $983\ 00:38:44.820$ --> 00:38:47.240 those parameters have error associated with them.
- 984 00:38:47.240 --> 00:38:48.086 Right?
- 985 00:38:48.086 --> 00:38:49.430 And you can imagine that the bigger your selected sample,
- $986\ 00:38:49.430 \longrightarrow 00:38:51.490$ the more precisely estimating those betas,
- 987 00:38:51.490 --> 00:38:52.900 that's not being reflected
- $988\ 00:38:52.900 \longrightarrow 00:38:55.880$ at all in the modified maximum likelihood.
- 989 00:38:55.880 --> 00:38:57.420 So instead we can be Bayesian.
- $990\ 00:38:57.420 --> 00:39:00.520$ Put non-informative priors on all the identified parameters.
- 991 00:39:00.520 --> 00:39:01.920 That's gonna let those,
- 992 00:39:01.920 --> 00:39:04.640 the error in those betas be propagated.
- 993 00:39:04.640 --> 00:39:07.430 And so we'll incorporate that uncertainty.
- 994 00:39:07.430 \rightarrow 00:39:11.160 And we can actually, additionally put a prior on phi, right?
- 995 00:39:11.160 --> 00:39:11.993 So we could just say
- $996\ 00:39:11.993 \longrightarrow 00:39:14.300$ let's have it be uniform across zero one.
- 997 00:39:14.300 --> 00:39:15.133 Right?
- $998\ 00:39:15.133 \longrightarrow 00:39:17.540$ So we can see what does it look like if we in totality,
- 999 00:39:17.540 --> 00:39:20.360 if we assume that phi is somewhere evenly distributed
- $1000\ 00:39:20.360 \longrightarrow 00:39:21.610$ across that interval.
- $1001\ 00:39:21.610 \longrightarrow 00:39:22.870$ We've done other things as well.
- $1002\ 00:39:22.870 \longrightarrow 00:39:25.860$ We've taken like discreet priors.
- 1003 00:39:25.860 --> 00:39:28.960 Oh, let's put a point mass on 0.5 and one
- $1004\ 00:39:28.960 \longrightarrow 00:39:29.940$ or other different, right?

- 1005 00:39:29.940 --> 00:39:31.883 You can do whatever you want for that prior.
- $1006\ 00:39:32.880 \longrightarrow 00:39:34.560$ So let's go back to the example
- $1007\ 00:39:34.560 \longrightarrow 00:39:36.090$ see what it looks like.
- $1008\ 00{:}39{:}36.090 \dashrightarrow 00{:}39{:}38.300$ If we have the proportion ever married for females
- $1009\ 00:39:38.300 \longrightarrow 00:39:40.340$ on the left and males on the right,
- $1010\ 00:39:40.340 \longrightarrow 00:39:42.950$ the true bias is the black dot.
- $1011\ 00:39:42.950 \longrightarrow 00:39:45.070$ And so the black is the true bias.
- $1012\ 00:39:45.070 \longrightarrow 00:39:49.540$ The little tiny diamond is the MUBP for 0.5.
- 1013 00:39:49.540 --> 00:39:52.030 An so that's plugging in that average value.
- $1014\ 00:39:52.030 \dashrightarrow 00:39:55.780$ Some selection mechanism that depends on why some,
- $1015\ 00:39:55.780 \longrightarrow 00:39:56.850$ somewhere in the middle.
- 1016 00:39:56.850 --> 00:39:57.993 So we're actually coming pretty close.
- 1017 00:39:57.993 --> 00:40:00.210 That happens to be, that's pretty close.
- 1018 00:40:00.210 --> 00:40:01.750 And the intervals in green
- $1019\ 00{:}40{:}01.750 \dashrightarrow 00{:}40{:}04.040$ are the modified maximum likelihood intervals
- $1020\ 00:40:04.040$ --> 00:40:06.120 from phi equals zero to phi equals one,
- 1021 00:40:06.120 --> 00:40:08.240 and the Bayesian intervals are longer, right?
- 1022 00:40:08.240 --> 00:40:09.073 Naturally.
- 1023 00:40:09.073 --> 00:40:10.840 We're incorporating the uncertainty.
- 1024 00:40:10.840 --> 00:40:12.920 Essentially these MUBP,
- $1025\ 00{:}40{:}12.920 \dashrightarrow 00{:}40{:}14.767$ modified maximum likely intervals are too short.
- $1026\ 00:40:14.767 --> 00:40:17.103$ And we admit that these are too short.
- $1027\ 00:40:18.350 \longrightarrow 00:40:21.300$ If we plug in all zeros and all ones
- $1028~00{:}40{:}21.300 \dashrightarrow 00{:}40{:}25.380$ for that small proportion of my NSFG population
- $1029\ 00:40:25.380 \longrightarrow 00:40:27.310$ that we aren't selected into the sample,
- $1030\ 00:40:27.310 --> 00:40:31.160$ we get huge bounds relative to our indicator.
- 1031 00:40:31.160 --> 00:40:31.993 Right?

 $1032\ 00:40:31.993 \longrightarrow 00:40:33.560$ So remember when I showed you that slide, that bounded,

 $1033\ 00:40:33.560 \longrightarrow 00:40:36.810$ we know the bias has to be between these two values.

 $1034\ 00:40:36.810 \longrightarrow 00:40:37.790$ That's what's going on here.

 $1035\ 00:40:37.790 \longrightarrow 00:40:39.320$ That's what these two values are.

 $1036\ 00:40:39.320 \longrightarrow 00:40:41.480$ But using the information in Z

 $1037\ 00:40:41.480 \longrightarrow 00:40:43.260$ we're able to much, much narrow

 $1038\ 00{:}40{:}43.260 --> 00{:}40{:}45.780$ or make an estimate on where our selection bias is.

 $1039\ 00:40:45.780 \longrightarrow 00:40:47.670$ So we got much tighter bounds.

 $1040\ 00:40:47.670 \longrightarrow 00:40:48.503$ An important fact here

 $1041\ 00:40:48.503 \longrightarrow 00:40:50.420$ is that we have pretty good predictors.

1042 00:40:50.420 --> 00:40:52.620 Our correlation, the biserial correlation

 $1043\ 00:40:52.620 \longrightarrow 00:40:54.360$ is about 0.7 or 0.8.

 $1044\ 00:40:54.360 \longrightarrow 00:40:55.850$ So these things are pretty correlated

 $1045\ 00{:}40{:}55.850 \to 00{:}40{:}58.650$ with whether you've been married, age, education, right?

 $1046\ 00:40:58.650 \longrightarrow 00:41:00.400$ Those things are pretty correlated.

1047 00:41:01.310 --> 00:41:04.370 Another variable in the NSFG is income.

 $1048\ 00{:}41{:}04.370 \dashrightarrow 00{:}41{:}07.890$ So we can think about an indicator for having low income.

 $1049\ 00:41:07.890 \longrightarrow 00:41:10.130$ Well, as it turns out those variables

 $1050\ 00:41:10.130 --> 00:41:13.810$ we have on everybody; age, education, gender,

 $1051\ 00{:}41{:}13.810 \dashrightarrow 00{:}41{:}16.150$ those things are not actually that good of predictors,

 $1052\ 00:41:16.150 --> 00:41:18.720$ of low income, very low correlation.

 $1053\ 00:41:18.720 \longrightarrow 00:41:21.040$ So our index reflects that.

1054 00:41:21.040 --> 00:41:23.380 Or you get much, Y, your intervals.

 $1055\ 00:41:23.380 \longrightarrow 00:41:25.940$ Sort of closer to the Manski bounds.

 $1056\ 00{:}41{:}25.940 \dashrightarrow 00{:}41{:}28.770$ And in fact, it's exactly returning one of those bounds.

- $1057\ 00:41:28.770 --> 00:41:32.930$ The filling in all zeros bound is returned by this index.
- $1058\ 00:41:32.930 \longrightarrow 00:41:34.750$ So that's actually an attractive feature.
- 1059 00:41:34.750 --> 00:41:35.583 Right?
- $1060\ 00{:}41{:}35.583 --> 00{:}41{:}37.810$ We're sort of bounded at the worst possible case
- $1061\ 00:41:37.810 \longrightarrow 00:41:39.410$ on one end of the bias
- $1062\ 00:41:40.496 \longrightarrow 00:41:42.260$ but we are still capturing the truth.
- 1063 00:41:42.260 --> 00:41:44.150 The Manski bounds are basically useless,
- $1064\ 00:41:44.150 --> 00:41:45.650$ right in this particular case.
- $1065\ 00:41:47.210 \longrightarrow 00:41:50.278$ So that's a toy example.
- 1066 00:41:50.278 --> 00:41:53.060 Just gonna quickly show you a real example,
- 1067 00:41:53.060 --> 00:41:54.010 and I'm actually gonna to skip
- 1068 00:41:54.010 --> 00:41:55.190 over the incentive experiment,
- $1069\ 00:41:55.190 --> 00:41:57.070$ which well, very, very interesting
- $1070\ 00:41:57.070 \longrightarrow 00:41:59.160$ is there's a lot to talk about,
- $1071\ 00{:}41{:}59.160 \dashrightarrow 00{:}42{:}01.943$ and I'd rather jump straight to the presidential polls.
- 1072 00:42:03.210 --> 00:42:07.633 So there's very much in the news now,
- $1073\ 00:42:07.633 \longrightarrow 00:42:08.466$ and over the past several years,
- 1074 00:42:08.466 --> 00:42:10.900 this idea of failure of political polling
- $1075\ 00:42:10.900 --> 00:42:12.417$ and this recent high profile failure
- 1076 00:42:12.417 --> 00:42:14.930 of pre-election polls in the US.
- 1077 00:42:14.930 --> 00:42:17.500 So polls are probability samples
- $1078~00{:}42{:}17.500 \dashrightarrow 00{:}42{:}20.035$ but they have very, very, very low response rates.
- 1079~00:42:20.035 --> 00:42:21.100 I don't know how much you know about how they're done,
- 1080 00:42:21.100 --> 00:42:23.100 but they're very, very low response rate.
- $1081\ 00:42:23.100 --> 00:42:25.230$ But think about what we're getting at in a poll,
- $1082\ 00{:}42{:}25.230 \to 00{:}42{:}28.450$ a binary variable, are you going to vote for Donald Trump?

- $1083\ 00:42:28.450 \longrightarrow 00:42:29.283$ Yes or no?
- $1084\ 00:42:29.283 --> 00:42:30.520$ Are you gonna vote for Joe Biden?
- $1085\ 00:42:30.520 \longrightarrow 00:42:31.353$ Yes or no?
- $1086\ 00:42:31.353 \longrightarrow 00:42:32.186$ These binary variables.
- $1087\ 00:42:32.186 \longrightarrow 00:42:33.750$ We want to estimate proportions.
- $1088\ 00:42:33.750 \longrightarrow 00:42:35.550$ That's what political polls aimed to do.
- $1089\ 00:42:35.550 \longrightarrow 00:42:37.350$ Pre-election polls.
- $1090\ 00{:}42{:}37.350 \dashrightarrow 00{:}42{:}40.620$ So we have these political polls with these failures.
- $1091\ 00{:}42{:}40.620 \dashrightarrow 00{:}42{:}43.580$ So we're thinking, maybe it's a selection bias problem.
- $1092\ 00:42:43.580 \longrightarrow 00:42:45.390$ And that there is some of this people
- $1093\ 00:42:45.390 --> 00:42:49.210$ are entering into this poll differentially,
- $1094\ 00:42:49.210 \longrightarrow 00:42:51.730$ depending on who they're going to vote for.
- $1095\ 00:42:51.730 \longrightarrow 00:42:52.760$ So think of it this way,
- $1096\ 00:42:52.760 --> 00:42:54.130$ and I'm gonna use Trump as the example
- 1097 00:42:54.130 --> 00:42:55.320 'cause we're going to estimate,
- 1098 00:42:55.320 --> 00:42:56.153 I'm gonna try to estimate
- 1099 00:42:56.153 --> 00:42:57.498 the proportion of people who will vote
- $1100\ 00{:}42{:}57.498 {\: -->\:} 00{:}43{:}01.900$ for Former President Trump in the 2020 election.
- 1101 00:43:01.900 --> 00:43:04.320 So, might Trump supporters
- $1102\ 00{:}43{:}04.320 \dashrightarrow 00{:}43{:}07.120$ just inherently be less likely to answer the call, right?
- $1103\ 00{:}43{:}07.120 \dashrightarrow 00{:}43{:}10.760$ To answer that poll or to refuse to answer the question
- $1104\ 00{:}43{:}10.760 \operatorname{--}> 00{:}43{:}13.440$ even conditional demographic characteristics, right?
- $1105\ 00:43:13.440 \longrightarrow 00:43:15.900$ So two people who otherwise look the same
- $1106\ 00:43:15.900 \longrightarrow 00:43:19.730$ with respect to those Z variables, age, race, education,
- $1107\ 00{:}43{:}19.730 \dashrightarrow 00{:}43{:}22.160$ the one who's the Trump supporter, someone might argue,

- $1108\ 00{:}43{:}22.160 \dashrightarrow 00{:}43{:}24.260$ you might be more suspicious of the government
- $1109\ 00:43:24.260 \longrightarrow 00:43:25.820$ and the polls, and not want to answer
- $1110\ 00:43:25.820 \longrightarrow 00:43:28.460$ and not come into this poll, not be selected.
- 1111 00:43:28.460 --> 00:43:30.910 As it would be depending on why.
- $1112\ 00:43:30.910 \longrightarrow 00:43:35.240$ So the MUBP could be used to try to adjust poll estimates.
- 1113 00:43:35.240 --> 00:43:37.810 Say, well, there's your estimate from the poll
- 1114 00:43:37.810 --> 00:43:40.200 but what if selection were not ignorable?
- 1115 00:43:40.200 --> 00:43:41.690 How different would our estimate
- 1116 00:43:41.690 --> 00:43:43.440 of the proportion voting for Trump?
- $1117\ 00:43:44.700 \longrightarrow 00:43:47.790$ So in this example, our proportion of interest
- $1118\ 00:43:47.790 \longrightarrow 00:43:51.300$ is the percent of people who are gonna vote for Trump.
- $1119\ 00:43:51.300 \longrightarrow 00:43:52.950$ The sample that we used
- $1120\ 00:43:52.950 \longrightarrow 00:43:54.420$ are publicly available data
- 1121 00:43:54.420 --> 00:43:56.390 from seven different pre-election polls
- $1122\ 00:43:56.390 --> 00:44:00.530$ conducted in seven different states by ABC in 2020.
- $1123\ 00:44:00.530 \longrightarrow 00:44:02.760$ And the way these polls work
- $1124\ 00:44:02.760 --> 00:44:04.830$ is it's a random digit dialing survey.
- $1125\ 00{:}44{:}04.830 \dashrightarrow 00{:}44{:}07.770$ So that's literally randomly dialing phone numbers.
- 1126 00:44:07.770 --> 00:44:08.650 Many of whom get
- 1127 00:44:08.650 --> 00:44:10.340 throughout 'cause their business, et cetera,
- $1128\ 00:44:10.340 \longrightarrow 00:44:12.960$ very, very low response rates, 10% or lower.
- $1129\ 00{:}44{:}12.960 \dashrightarrow 00{:}44{:}16.810$ Very, very, very low response rates to these kinds of polls.
- 1130 00:44:16.810 --> 00:44:19.290 They do, however, try to do some weighting.
- $1131\ 00:44:19.290 \longrightarrow 00:44:20.810$ So it's not as if they just take that sample and say,
- $1132\ 00{:}44{:}20.810 \dashrightarrow 00{:}44{:}23.490$ there we go let's estimate the proportion for Trump.

- $1133\ 00:44:23.490 \longrightarrow 00:44:24.730$ We do waiting adjustments
- $1134\ 00{:}44{:}24.730 \dashrightarrow 00{:}44{:}28.300$ and they use what's called inter proportional fitting
- $1135\ 00{:}44{:}28.300 \dashrightarrow 00{:}44{:}32.820$ or raking to get the distribution of key variables
- $1136\ 00:44:32.820 \longrightarrow 00:44:35.660$ in the sample to look like the population.
- 1137 00:44:35.660 --> 00:44:37.620 So they use census margins for, again,
- 1138 00:44:37.620 --> 00:44:40.460 it's gender as binary, unfortunately,
- $1139\ 00{:}44{:}40.460 \dashrightarrow 00{:}44{:}43.913$ age, education, race, ethnicity, and party identification.
- $1140\ 00:44:44.800 \longrightarrow 00:44:46.870$ So, because we're doing this after the election
- $1141\ 00:44:46.870 \longrightarrow 00:44:47.730$ we know the truth.
- $1142\ 00{:}44{:}47.730 \dashrightarrow 00{:}44{:}50.250$ We have access to the true official election outcomes
- $1143\ 00:44:50.250 \longrightarrow 00:44:51.210$ in each state.
- 1144 00:44:51.210 --> 00:44:53.780 So I know the actual proportion of why.
- 1145 00:44:53.780 --> 00:44:56.590 And my population is likely voters,
- 1146 00:44:56.590 --> 00:44:58.460 because that's who we're trying to target
- $1147\ 00:44:58.460 \longrightarrow 00:44:59.427$ with these pre-election polls.
- $1148\ 00{:}44{:}59.427 \dashrightarrow 00{:}45{:}02.290$ You wanna know what's the estimated proportion
- $1149\ 00{:}45{:}02.290 \dashrightarrow 00{:}45{:}04.950$ would vote for Trump among the likely voters.
- $1150\ 00:45:04.950 \longrightarrow 00:45:07.000$ So the tricky thing is that population
- 1151 00:45:07.000 --> 00:45:09.930 is hard to come by summary statistics.
- 1152 00:45:09.930 --> 00:45:11.170 Likely voters, right?
- $1153\ 00{:}45{:}11.170 \dashrightarrow 00{:}45{:}13.440$ It's easy to get summary statistics from all people
- $1154\ 00{:}45{:}13.440 --> 00{:}45{:}16.030$ in the US or all people of voting age in the US
- $1155\ 00:45:16.030 \longrightarrow 00:45:17.467$ but not likely voters.
- $1156\ 00{:}45{:}18.380 \dashrightarrow 00{:}45{:}21.340$ So here Y is an indicator for voting for Trump.
- $1157\ 00:45:21.340 \longrightarrow 00:45:24.310\ Z$ is auxiliary variable in the ABC poll.

- $1158\ 00:45:24.310 \longrightarrow 00:45:25.410$ So all those variables I mentioned
- $1159\ 00:45:25.410 \longrightarrow 00:45:27.480$ before gender age, et cetera.
- 1160 00:45:27.480 --> 00:45:29.270 We actually have very strong predictors
- $1161\ 00:45:29.270 \longrightarrow 00:45:32.260$ of why basically because of these political ideation,
- 1162 00:45:32.260 --> 00:45:33.980 party identification variables, right?
- $1163\ 00:45:33.980 \longrightarrow 00:45:36.820$ Not surprisingly the people who identify as Democrats,
- $1164\ 00:45:36.820 \longrightarrow 00:45:39.263$ very unlikely to be voting for Trump.
- $1165\ 00{:}45{:}40.670 {\:{\mbox{--}}\!>} 00{:}45{:}44.080$ The data set that we found that can give us population level
- $1166\ 00{:}45{:}44.080 \dashrightarrow 00{:}45{:}47.630$ estimates of the mean of Z for the non-selected sample
- $1167\ 00:45:47.630 \longrightarrow 00:45:49.890$ is a dataset from AP/NORC.
- $1168\ 00:45:49.890 \longrightarrow 00:45:51.700$ It's called their VoteCast Data.
- 1169 00:45:51.700 --> 00:45:54.690 And they conduct these large surveys
- 1170 00:45:54.690 --> 00:45:57.770 and provide an indicator of likely voter.
- $1171\ 00:45:57.770 \longrightarrow 00:46:00.370$ So we can basically use this dataset
- $1172\ 00:46:00.370 \longrightarrow 00:46:02.280$ to describe the demographic characteristics
- 1173 00:46:02.280 --> 00:46:03.520 of likely voters,
- $1174\ 00{:}46{:}03.520$ --> $00{:}46{:}07.503$ instead of just all people who are 18 and older in the US.
- $1175\ 00:46:08.520 \longrightarrow 00:46:10.260$ The subtle issue is of course,
- $1176\ 00:46:10.260 --> 00:46:12.530$ these AP VoteCast data are not without error,
- $1177\ 00:46:12.530 \longrightarrow 00:46:15.070$ but we're going to pretend that they are without error.
- $1178\ 00:46:15.070 \longrightarrow 00:46:16.530$ And that's like a whole other papers.
- 1179 00:46:16.530 --> 00:46:17.363 How do we handle the fact
- 1180 00:46:17.363 --> 00:46:19.350 that my population data have error?
- $1181\ 00{:}46{:}19.350 \dashrightarrow 00{:}46{:}22.610$ So we're gonna use the unweighted ABC poll data
- $1182\ 00{:}46{:}22.610$ --> $00{:}46{:}25.530$ as the selected sample and estimate the MUBP

- 1183 00:46:25.530 --> 00:46:27.270 with the Bayesian approach with phi
- $1184\ 00:46:27.270 \longrightarrow 00:46:29.270$ from the uniform distribution.
- $1185\ 00{:}46{:}29.270 --> 00{:}46{:}32.280$ The poll selection fraction is very, very small.
- 1186 00:46:32.280 --> 00:46:34.030 Right, these polls in each state
- $1187\ 00:46:34.030 \longrightarrow 00:46:36.050$ have about a thousand people in them
- $1188\ 00:46:36.050 \longrightarrow 00:46:38.060$ but we've got millions of voters in each state.
- $1189\ 00:46:38.060 --> 00:46:40.040$ So the selection fraction is very, very small,
- $1190\ 00{:}46{:}40.040 \dashrightarrow 00{:}46{:}42.090$ total opposite of the smartphone example.
- 1191 00:46:42.980 --> 00:46:45.760 So we'll just jump straight into the answer,
- 1192 00:46:45.760 --> 00:46:46.593 did it work?
- 1193 00:46:46.593 --> 00:46:48.090 Right, this is really exciting.
- 1194 00:46:48.090 --> 00:46:51.820 So the red circle is the true proportion,
- 1195 00:46:51.820 --> 00:46:53.410 oh, sorry, the true bias,
- $1196\ 00:46:53.410 \longrightarrow 00:46:54.720$ this should say bias down here.
- $1197\ 00:46:54.720 \longrightarrow 00:46:55.600$ In each of the states.
- $1198\ 00:46:55.600 \longrightarrow 00:46:56.540$ So these are the seven states
- 1199 00:46:56.540 --> 00:46:59.270 we looked at Arizona, Florida, Michigan, Minnesota,
- $1200\ 00{:}46{:}59.270 \dashrightarrow 00{:}47{:}01.550$ North Carolina, Pennsylvania, and Wisconsin
- $1201\ 00:47:01.550 \dashrightarrow 00:47:05.960$ So this horizontal line here at zero that's no bias, right?
- 1202 00:47:05.960 --> 00:47:08.140 So it's estimated, the ABC poll estimate
- $1203\ 00:47:08.140 \longrightarrow 00:47:09.490$ would have no bias.
- $1204\ 00{:}47{:}09.490 \dashrightarrow 00{:}47{:}12.920$ And we can see then in Arizona where sort of overestimated
- $1205\ 00:47:12.920 \longrightarrow 00:47:14.060$ and in the rest of the states
- $1206\ 00:47:14.060 \longrightarrow 00:47:16.277$ we've got underestimated the support for Trump.
- $1207\ 00{:}47{:}16.277 \dashrightarrow 00{:}47{:}19.140$ And so that was really the failure was the underestimation

- $1208\ 00:47:19.140 \longrightarrow 00:47:20.290$ of the support for Trump.
- $1209\ 00:47:20.290 --> 00:47:23.880$ Notice that our Bayesian bounds
- 1210 00:47:23.880 --> 00:47:26.230 cover the true bias everywhere except
- 1211 00:47:26.230 --> 00:47:27.920 in Pennsylvania and Wisconsin.
- 1212 00:47:27.920 --> 00:47:30.430 And so Wisconsin had an enormous bias,
- 1213 00:47:30.430 --> 00:47:32.570 or they way under called the support for Trump
- 1214 00:47:32.570 --> 00:47:34.470 in Wisconsin by 10 percentage points.
- 1215 00:47:34.470 --> 00:47:35.410 Huge problem.
- $1216\ 00:47:35.410 \longrightarrow 00:47:36.850$ So we're not getting there
- $1217\ 00:47:36.850 \longrightarrow 00:47:39.880$ but notice that zero is not in our interval.
- 1218 00:47:39.880 --> 00:47:42.760 So our bounds are suggesting
- $1219\ 00:47:42.760 \longrightarrow 00:47:45.530$ that there was a negative bias from the poll.
- 1220 00:47:45.530 --> 00:47:47.660 So even though we didn't capture the truth,
- $1221\ 00:47:47.660 \longrightarrow 00:47:49.260$ we've at least crossed the threshold
- 1222 00:47:49.260 --> 00:47:52.360 saying very likely that you are under calling
- $1223\ 00:47:52.360 \longrightarrow 00:47:54.023$ the support for Trump.
- $1224\ 00:47:55.280$ --> 00:47:59.200 So how do estimates using the MUBP compared to the ABC poll?
- $1225\ 00{:}47{:}59.200 \dashrightarrow 00{:}48{:}02.830$ Well, we can use the MUBP bounds to basically shift
- $1226\ 00:48:02.830 \longrightarrow 00:48:04.570$ the ABC poll estimates.
- 1227 00:48:04.570 --> 00:48:07.740 So we're calling those MUBP adjusted, right?
- $1228\ 00:48:07.740 \longrightarrow 00:48:09.850$ So we've got the truth is...
- 1229 00:48:09.850 --> 00:48:11.590 The true proportion who voted for Trump
- $1230\ 00:48:11.590 \longrightarrow 00:48:14.360$ are now these red triangles
- $1231\ 00{:}48{:}14.360 \dashrightarrow 00{:}48{:}17.290$ and then the black circles are the point estimates
- 1232 00:48:17.290 --> 00:48:19.810 from three different methods of estimation,
- $1233\ 00:48:19.810 \longrightarrow 00:48:21.450$ of obtaining an estimate.
- $1234\ 00{:}48{:}21.450 \dashrightarrow 00{:}48{:}24.720$ Unweighted from the poll weighted estimate from the poll

- $1235\ 00:48:24.720 \longrightarrow 00:48:27.820$ and the adjusted by our measure of selection bias,
- $1236\ 00{:}48{:}27.820 \dashrightarrow 00{:}48{:}30.340$ the non-ignorable selection bias is the last one.
- $1237\ 00:48:30.340 \longrightarrow 00:48:32.330$ Is MUBP adjusted.
- $1238\ 00:48:32.330 \longrightarrow 00:48:34.850$ So we can see that in some cases
- $1239\ 00:48:34.850 \longrightarrow 00:48:39.140$ our adjustment and the polls are pretty similar, right?
- 1240 00:48:39.140 --> 00:48:40.700 But look at, for example, Wisconsin,
- $1241\ 00:48:40.700 \longrightarrow 00:48:42.080$ all the way over here on the right.
- $1242\ 00{:}48{:}42.080 \dashrightarrow 00{:}48{:}43.887$ So again, remember I said, we didn't cover the truth
- $1243\ 00:48:43.887 \longrightarrow 00:48:45.700$ and we didn't cover the true bias
- 1244 00:48:45.700 --> 00:48:48.650 but our indicator is the only one, right?
- $1245\ 00{:}48{:}48.650 --> 00{:}48{:}52.020$ That's got that much higher shift up towards Trump.
- $1246\ 00:48:52.020 \longrightarrow 00:48:53.430$ So this is us saying, well,
- $1247~00{:}48{:}53.430 \dashrightarrow 00{:}48{:}57.190$ if there were an underlying selection mechanism
- 1248 00:48:57.190 --> 00:48:58.980 saying that Trump supporters
- 1249 00:48:58.980 --> 00:49:02.860 were inherently less likely to enter this poll,
- $1250\ 00:49:02.860 \longrightarrow 00:49:03.900$ this is what would happen.
- $1251\ 00:49:03.900 --> 00:49:07.330$ Or this is what your estimated support for Trump would be.
- 1252 00:49:07.330 --> 00:49:08.830 It's shifted up.
- 1253 00:49:08.830 --> 00:49:10.780 We've got a similar sort of success story
- $1254\ 00:49:10.780 \longrightarrow 00:49:12.270$ I'll say in Minnesota,
- $1255\ 00{:}49{:}12.270 \dashrightarrow 00{:}49{:}15.650$ we're both of the ABC estimators did not cover the truth
- 1256 00:49:15.650 --> 00:49:18.000 in these pre-election polls but ours did, right.
- 1257 00:49:18.000 --> 00:49:20.660 We were able to sort of shift up and say,
- $1258\ 00:49:20.660 \longrightarrow 00:49:22.440$ look, if there were selection bias
- $1259~00{:}49{:}22.440 \dashrightarrow 00{:}49{:}24.660$ that depended on whether or not you supported Trump

- $1260\ 00:49:24.660 \longrightarrow 00:49:26.900$ we would we captured that.
- 1261 00:49:26.900 --> 00:49:29.060 So the important idea here is, you know,
- $1262\ 00:49:29.060 \longrightarrow 00:49:33.630$ before the election, we wouldn't have these red triangles.
- $1263\ 00:49:33.630 \longrightarrow 00:49:35.620$ But it's important to be able to see
- 1264 00:49:35.620 --> 00:49:38.600 that this is saying you're under calling
- 1265 00:49:38.600 --> 00:49:39.870 the support for Trump
- $1266\ 00:49:39.870 \longrightarrow 00:49:42.330$ if there were a non-negligible selection, right?
- 1267 00:49:42.330 --> 00:49:44.070 So it's that idea of a sensitivity analysis?
- 1268 00:49:44.070 --> 00:49:46.130 How bad would we be doing?
- $1269\ 00{:}49{:}46.130 \dashrightarrow 00{:}49{:}48.780$ And what we would say is in Minnesota and Wisconsin
- 1270 00:49:48.780 --> 00:49:49.960 we'd be very worried
- 1271 00:49:49.960 --> 00:49:53.083 about under calling the support for Trump.
- 1272 00:49:56.280 --> 00:49:59.370 So what have I just shown you?
- 1273 00:49:59.370 --> 00:50:00.530 I'll summarize.
- $1274\ 00:50:00.530 \longrightarrow 00:50:03.900$ The MUBP is a sensitivity analysis tool
- $1275\ 00:50:03.900 --> 00:50:07.780$ to assess the potential for non-ignorable selection bias.
- $1276\ 00:50:07.780 --> 00:50:11.640$ If we have a phi equals zero, an ignorable selection,
- 1277 00:50:11.640 --> 00:50:14.110 we can adjust that away via weighting
- 1278 00:50:14.110 --> 00:50:15.850 or some other method, right?
- $1279\ 00:50:15.850 --> 00:50:18.140$ So if it's not ignorable, I mean, if it is ignorable
- $1280\ 00:50:18.140 \longrightarrow 00:50:20.530$ we can ignore the selection mechanism.
- $1281\ 00:50:20.530 \longrightarrow 00:50:22.750$ On the other extreme if phi is one,
- 1282 00:50:22.750 --> 00:50:23.970 totally not ignorable,
- 1283 00:50:23.970 --> 00:50:26.030 selection is only depending on that outcome
- $1284\ 00:50:26.030 \longrightarrow 00:50:27.560$ we're trying to measure.
- $1285\ 00:50:27.560 \longrightarrow 00:50:29.550$ Somewhere in between we've got the 0.5.
- $1286\ 00:50:29.550 \longrightarrow 00:50:31.970$ That if you really needed a point estimate

 $1287\ 00:50:31.970 \longrightarrow 00:50:33.610$ of the bias, that would be 0.5.

 $1288\ 00:50:33.610 \longrightarrow 00:50:36.630$ And in fact, that's what this black dot is.

 $1289\ 00:50:36.630 --> 00:50:40.003$ That's the adjustment at 0.5 for our adjusted estimator.

1290 00:50:41.420 --> 00:50:45.210 This MUBP is tailored to binary outcomes,

 $1291\ 00:50:45.210$ --> 00:50:47.923 and it is an improvement over the normal base SMUB.

1292 00:50:47.923 --> 00:50:48.980 I didn't show you the,

 $1293\ 00:50:48.980 --> 00:50:51.930$ so the results from simulations that basically show

 $1294~00{:}50{:}51.930 \dashrightarrow 00{:}50{:}54.550$ if you use the normal method on a binary outcome

 $1295\ 00:50:54.550 \longrightarrow 00:50:56.020$ you get these huge bounds.

1296 00:50:56.020 --> 00:50:58.180 You go outside of the Manski bounds, right?

 $1297\ 00:50:58.180 --> 00:51:01.010$ 'Cause it's not properly bounded between zero and one,

1298 00:51:01.010 --> 00:51:03.300 or your proportion isn't properly bounded.

1299 00:51:03.300 --> 00:51:05.910 And importantly, our measure only requires

 $1300\ 00:51:05.910 \longrightarrow 00:51:08.140$ summary statistics for Z,

 $1301\ 00:51:08.140 \longrightarrow 00:51:11.160$ for the population or for the non-selected sample.

 $1302\ 00{:}51{:}11.160 \dashrightarrow 00{:}51{:}13.750$ So I don't have to have a whole separate data set

 $1303\ 00{:}51{:}13.750 --> 00{:}51{:}15.660$ where I have every body who didn't get selected

1304 00:51:15.660 --> 00:51:16.493 into my sample,

 $1305\ 00:51:16.493 \longrightarrow 00:51:19.703\ I$ just need to know the average of these co-variants, right.

 $1306~00{:}51{:}19.703 \dashrightarrow 00{:}51{:}23.380~\mathrm{I}$ just needs to know Z-bar in order to get my average

 $1307\ 00:51:23.380 \longrightarrow 00:51:25.580$ proxy for the non-selected.

1308 00:51:25.580 --> 00:51:27.100 With weak information,

 $1309~00{:}51{:}27.100$ --> $00{:}51{:}30.410$ so if my model is poor then my Manski bounds

- $1310\ 00:51:30.410 \longrightarrow 00:51:31.560$ are gonna be what's returned.
- $1311\ 00:51:31.560 \longrightarrow 00:51:34.200$ So that's a good feature of this index.
- 1312 00:51:34.200 --> 00:51:35.670 Is that it is naturally bound
- $1313\ 00:51:35.670 --> 00:51:38.000$ unlike the normal model version.
- $1314\ 00:51:38.000 \longrightarrow 00:51:41.020$ And we have done additional work to move
- $1315\ 00{:}51{:}41.020 \dashrightarrow 00{:}51{:}43.140$ beyond just estimating means and proportions
- $1316\ 00{:}51{:}43.140 {\: -->\:} 00{:}51{:}45.950$ into linear regression and probate progression.
- $1317\ 00:51:45.950 --> 00:51:48.360$ So we've have indices of selection bias
- $1318\ 00:51:48.360 \longrightarrow 00:51:49.630$ for regression coefficients.
- 1319 00:51:49.630 --> 00:51:52.780 So instead of wanting to know the mean of Y
- 1320 00:51:52.780 --> 00:51:54.900 or the proportion with Y equals one,
- $1321\ 00:51:54.900 --> 00:51:57.210$ what if you wanted to do a regression of Y
- $1322\ 00:51:57.210 \longrightarrow 00:51:58.700$ on some covariates?
- $1323\ 00{:}51{:}58.700 \dashrightarrow 00{:}52{:}01.590$ So we have a paper out in the animals of applied statistics
- $1324\ 00:52:01.590 \longrightarrow 00:52:04.750$ that extends those two regression coefficients.
- $1325\ 00:52:04.750 \dashrightarrow 00:52:06.740$ So I believe I'm pretty much right on the time
- $1326~00{:}52{:}06.740 --> 00{:}52{:}09.240~\mathrm{I}$ was supposed to end, so I'll say Thank you everyone.
- 1327 00:52:09.240 --> 00:52:11.170 And I'm happy to take questions.
- 1328 00:52:11.170 --> 00:52:12.250 I'll put on my references
- 1329 00:52:12.250 --> 00:52:15.423 of my meeny, miny fonts, yes.
- 1330 00:52:19.810 --> 00:52:21.960 Robert Does anybody have any questions?
- $1331\ 00:52:25.610 \longrightarrow 00:52:26.443$ From the room?
- $1332\ 00:52:33.498 \longrightarrow 00:52:34.331\ So.$
- $1333\ 00:52:36.340 --> 00:52:37.820\ Dr.$ Rebecca Let me stop my share.
- 1334 00:52:37.820 --> 00:52:38.653 Student Hey.
- $1335\ 00:52:39.630 \longrightarrow 00:52:41.360$ I have a very basic one,
- 1336 00:52:41.360 --> 00:52:43.740 mostly more of curiosity (indistinct)

- 1337 00:52:43.740 --> 00:52:45.360 Sure, sure.
- $1338\ 00:52:45.360 \longrightarrow 00:52:47.260$ What is it that caused the...
- $1339\ 00:52:49.970 \longrightarrow 00:52:53.710$ We know after the fact that in your example
- $1340\ 00:52:53.710 \longrightarrow 00:52:56.907$ that there was the direction of the bias,
- $1341\ 00:52:56.907 --> 00:53:01.907$ but why is it that it only shifted in the Trump direction?
- $1342\ 00:53:02.570 \longrightarrow 00:53:03.403$ Why?
- $1343\ 00:53:03.403 \longrightarrow 00:53:05.520$ You don't know in advance if something is more likely
- $1344\ 00:53:05.520 \longrightarrow 00:53:06.353$ or less likely?
- 1345 00:53:07.831 --> 00:53:08.664 Okay.
- $1346\ 00:53:08.664 \longrightarrow 00:53:09.497$ So excellent question.
- $1347\ 00:53:09.497 --> 00:53:11.330$ So that is effectively,
- $1348\ 00:53:11.330 \longrightarrow 00:53:14.750$ the direction of the shift is going to match...
- $1349\ 00:53:14.750 \longrightarrow 00:53:16.673$ The direction of the shift in the mean of Y,
- $1350\ 00:53:16.673 --> 00:53:18.410$ when the proportion is going to match
- 1351 00:53:18.410 --> 00:53:20.250 the shift in X, right?
- $1352\ 00:53:20.250 --> 00:53:25.080$ So if what you get as your mean for your proxy,
- $1353\ 00:53:25.080 \longrightarrow 00:53:28.440$ for the non-selected sample is bigger
- $1354\ 00:53:28.440 --> 00:53:29.760$ than for your selected sample
- $1355\ 00:53:29.760 \longrightarrow 00:53:31.100$ then your proportion is gonna get shifted
- $1356\ 00:53:31.100 \longrightarrow 00:53:32.130$ in that direction?
- $1357\ 00:53:32.130 \longrightarrow 00:53:32.963$ Right.
- 1358 00:53:32.963 --> 00:53:36.660 It's only ever going to shift it to match the bias in X.
- 1359 00:53:36.660 --> 00:53:37.493 Right?
- 1360 00:53:37.493 --> 00:53:38.910 And so then, which way that shifts Y
- 1361 00:53:38.910 --> 00:53:40.530 depends on what the relationship
- $1362\ 00:53:40.530$ --> 00:53:45.530 is between the covariates Z and X in the probate regression.
- $1363\ 00{:}53{:}45.610 --> 00{:}53{:}49.380$ But it will always shift it in a particular direction.

- 1364 00:53:49.380 --> 00:53:51.980 I will notice that I fully admit,
- $1365\ 00:53:51.980 \longrightarrow 00:53:54.990$ our index actually shifted the wrong direction
- $1366\ 00:53:54.990 \longrightarrow 00:53:56.520$ in one particular case.
- 1367 00:53:56.520 --> 00:53:57.353 Right?
- $1368\ 00:53:57.353 \longrightarrow 00:53:58.823$ So actually in Florida,
- $1369\ 00:54:00.165 --> 00:54:02.170$ we actually shifted down when we shouldn't.
- 1370 00:54:02.170 --> 00:54:03.003 Right.
- $1371\ 00:54:03.003 \longrightarrow 00:54:05.270$ So here's the way to estimate and we're shifting down,
- $1372\ 00:54:05.270 \longrightarrow 00:54:06.790$ but actually the truth is higher.
- 1373 00:54:06.790 --> 00:54:08.810 So we're not always getting it right
- 1374 00:54:08.810 --> 00:54:12.500 we're getting it right when that X is shifting
- $1375\ 00:54:12.500 \longrightarrow 00:54:13.710$ in the correct direction.
- 1376 00:54:13.710 --> 00:54:14.543 Right?
- $1377\ 00:54:14.543 \longrightarrow 00:54:16.750$ So it isn't true that we always...
- 1378 00:54:16.750 --> 00:54:19.080 It's true that it always shifts the direction of X,
- 1379 00:54:19.080 --> 00:54:21.540 but it's not a hundred percent true that X
- $1380\ 00:54:21.540 \longrightarrow 00:54:23.740$ always shifts in the exact same way as Y.
- $1381\ 00:54:23.740 \longrightarrow 00:54:25.030$ Just most of the time.
- $1382\ 00{:}54{:}25.030 \dashrightarrow 00{:}54{:}28.950$ There was evidence of underestimating the Trump support,
- $1383\ 00:54:28.950 --> 00:54:31.600$ and that was in fact reflected in that probate regression,
- $1384\ 00:54:31.600 \longrightarrow 00:54:33.150$ right in that relationship.
- $1385\ 00:54:33.150 \longrightarrow 00:54:36.320$ The people who replied to the poll were older,
- 1386 00:54:36.320 --> 00:54:38.860 they were higher educated, right?
- 1387 00:54:38.860 --> 00:54:39.780 And so those older,
- 1388 00:54:39.780 --> 00:54:42.660 higher educated people in aggregate
- $1389\ 00:54:42.660 \longrightarrow 00:54:45.080$ were less likely to vote for Trump.
- $1390\ 00{:}54{:}45.080 \dashrightarrow 00{:}54{:}47.740$ So that's why we ended up under calling the support

- 1391 00:54:47.740 --> 00:54:49.290 for Trump when we don't account
- $1392\ 00:54:49.290$ --> 00:54:52.480 for that potential non-ignorable selection bias.
- $1393\ 00:54:52.480 \longrightarrow 00:54:53.637$ Good question though.
- $1394\ 00:54:54.520 --> 00:54:56.400$ Robert Go it, Thank you.
- $1395\ 00:54:56.400 \longrightarrow 00:54:59.460$ Any other questions (indistinct)
- 1396 00:55:09.360 --> 00:55:10.193 Anybody?
- $1397\ 00:55:15.900 --> 00:55:18.750\ I\ know\ I\ talk\ fast\ and\ that\ was\ a\ lot\ of\ stuff$
- $1398\ 00:55:18.750 --> 00:55:21.093$ so you know, like get it.
- $1399\ 00:55:21.093 \longrightarrow 00:55:23.070$ (indistinct)
- $1400\ 00:55:23.070 \longrightarrow 00:55:23.903$ Alright.
- $1401\ 00:55:23.903 --> 00:55:25.800$ Well, Andridge, Thank you again.
- $1402\ 00:55:25.800 \longrightarrow 00:55:26.882$ And.
- 1403 00:55:26.882 --> 00:55:29.882 (students clapping)
- $1404\ 00:55:32.950 \longrightarrow 00:55:33.783$ Thank you.
- $1405\ 00:55:33.783 \longrightarrow 00:55:34.960$ Thank you for having me.
- $1406\ 00:55:34.960 --> 00:55:35.793$ Robert Yeah.
