So, I'm Dr. Kai Chan,

Assistant Professor of the EHS Department.

I'm also the Director of Research for the center.

So today, we are very honored and prepared to have Dr. Lewis Ziska come to give us today's lecture.

So Dr. Ziska is a professor at the Mailman School of Public Health at Columbia University.

So before joining Columbia, he was a senior scientist at the US Department of Agriculture for nearly 25 years.

So he's one of the most leading experts on the effects of climate change on plants and agriculture.

So, without further ado, let's welcome Dr. Ziska.

Thank you, Professor Chan,

I appreciate the opportunity to be here.

The good news is you've got free food.

The bad news is you've got to listen to me lecture so...

I wanted to look at the nexus between climate change, rise in carbon dioxide and public health and just sort of give you a sense of the range
of different consequences associated with it. So we have the good, we have the bad, and we have the OMG. So, I want to go through and talk about some of the work that we’ve been doing on all of these different aspects.

Before I do that, however, I wanna make sure that we’re all on the same page when it comes to defining what we mean by climate change. So, we know that carbon dioxide is going up.

This is a recent Keeling Curve, where you can see that we’re getting close to about 410 parts per million. In my lifetime, the amount of carbon dioxide is increased by about 30% and the reason why is not difficult.

It turns out that if you take a carbon source, and you oxidize it, you burn it, carbon-oxygen, yeah carbon dioxide, who knew? So, if you look at, this is a little bit out of date, but if you look at where the carbon dioxide comes from, again, oxidation of fossil fuels and cement production in calcium carbonate, one of the offshoots of calcium carbonate is carbon dioxide.

Land use change, where does it go? About 50% of it stays in the atmosphere, about 25% of it goes back in the land through photosynthesis, and about 25% of it is dissolved into the oceans where carbon dioxide and water
is formed (mumbling) acid.
Okay, so...
here are as we know,
this particular change is recent.
This is the highest carbon dioxide that we’ve experienced,
at least in the last million years.
We know where it comes from, where is it gonna go?
Well, depends on which model you happen to believe in.
And I won’t go through all the different models.
We’ll look at the green one down here.
We’ll call this everyone drive a Prius and Hans model,
and that so far is not working out.
We have the business as usual model here,
and that may not be working out because that’s depending on
a certain amount of coal usage, and that’s been going down,
but there’s still a bit of uncertainty about the fact,
particularly in regards to methane,
but there’s no question that it’s going up.
If we just do the rule of thumb, it’s going up
two to three parts per million per year.
We have about 80 years left, so it can range anywhere
from 160 to 240 parts per million higher than it is today.
Okay, so why should you give a flying fig
whether carbon dioxide is 300 or 400 or 500,
Well, it makes two differences. The first one has to do with the physical aspects of increasing these particular gases. We know that the atmosphere consists of certain gases. Most of those we are familiar with, but there are two that we consider to be global warming gases. What does that mean exactly? What makes it a global warming gas? Well, to answer that question, I will, of course, turn to music.

How many of you have ever played a string instrument? Excellent, so I’m gonna turn this over to you. Suppose for the sake of argument that I tune two strings to the same frequency, okay? Let’s say A 440 Hertz, all right? So you have two strings that are tuned to the same frequency, and I pluck one string, what will the string next to it do? Suddenly vibrate? It’ll vibrate, it’ll resonate, it’ll absorb some of the energy from the first string. What if I’m a Methodist, will that still work? Are you telling me that the laws of physics still hold?
are independent of religious denomination and political affiliation?
Oh my god, you have no idea. (students laughing)
Oh wait, no, that isn’t how it works, is it?
Sorry, I’ve been in DC for too long.
Yeah, no it’s absolutely true.
So, what does this have to do with being a global warming gas?
Well, it turns out that in addition to music,
molecules also resonate.
They don’t resonate in the key of A,
but they resonate in the key of infrared, or heat.
So whenever heat is experienced by one of these molecules,
it resonates, it absorbs some of that energy
that would otherwise be lost, does that make sense?
Good, this has taken an entire semester
of physics and atmospheric chemistry
into five minutes so please forgive me.
- [Lewis] So the two major greenhouse gases
are carbon dioxide and water vapor, humidity, if you will.
All right?
So as this change in carbon dioxide occurs,
that’s not a bad thing because there’s a natural greenhouse effect.
If there were no carbon dioxide, the average temperature
on the earth would be about minus 80 degrees Celsius.
So, by having carbon dioxide, by having water vapor, you have a livable environment. But I think you can see that this sort of a Goldilocks principle that occurs here, right? Too little, too much. So, we’re seeing the earth warm up, but it’s not warming up the same everywhere, is it? Some areas are warming up faster than others. Why? Well, if it was the sun, then the equator would be warming up very fast. It’s not, what’s warming up the fastest? What area of the world is warming up quickly? The poles. They get the least amount of sun, how come they’re warming up so quickly? Wait a minute, I said there were two, there were two greenhouse gases, weren’t there? And, water vapor’s one of the greenhouse gases, so where on the globe is water vapor dominant, the dominant greenhouse gas? Where’s the air warming unit? I’m not trying to trick you. At the equator. So at the equatorial regions, where it’s warm and wet, you already have water vapor, it’s the dominant greenhouse gas.
Adding more CO2, yeah, it’s gonna get warmer and wetter. Is it gonna rise very quickly?

No, it takes a lot more energy to move something that has a lot of water in it, right? Because water absorbs heat.

Okay, so we got a big change in the tropics. Where is the air dry and therefore adding more carbon dioxide would be the primary driver, in terms of surface temperatures?

You already mentioned one. The Poles.

When the air is cold, it does not pull a lot of water vapor and therefore adding more carbon dioxide is going to have a major effect in terms of surface temperatures.

Where else is the air dry? Deserts, excellent.

So what do we expect to see with more carbon dioxide?

Increased desertification, right? Deserts are gonna get bigger.

Makes sense so far?
Okay, gonna add a little bit more to this. If you go up in elevation and altitude, as you move up in altitude the air becomes dryer, therefore there is gonna be a major shift in terms of temperature. Seasonally, which season, summer or winter, has the highest humidity? Connecticut, is it hotter and wetter in July or in December? Again, I'm not trying to trick you, okay? The summer is warmer and wetter, so the fact is that temperature is gonna happen more in the winter than it is in the summer, and that’s what we're seeing okay?

If water vapor is high, it’s the dominant warming gas, and there’s less effect of CO2. If the water vapor is low, adding more CO2 will have a differential higher effect with respect to surface temperatures. Again, I’ve taken an entire semester and given five minutes, but you can hopefully adjust to this, there’s more to it. Let’s look at it from the plant biology point of view. Okay, warmer temperatures, well,
with latitude or altitude, based on what I’ve talked about,
increased desertification, increased drought,
rise in sea levels from increased polar and glacial melt.
Okay?
So, what’s warm is gonna get warmer,
what’s wet is gonna get wetter,
and we see these changes going on, right?
That’s the indirect effect of rise in carbon dioxide.
Now, let me tell you the other direct effect,
the only direct effect,
and that is plants are essential to life.
What do plants need in order to grow?
Sunlight, excellent, thank you so much
for sitting in the front row.
Water, light, nutrients, right?
Carbon dioxide, right?
Okay, let’s do this as a thought experiment.
Suppose for the sake of argument that phosphorous, okay,
that the amount of phosphorous had gone up
in every soil around the world by 30%.
By 30% in your lifetime.
Would that have an effect on plant biology?
Yeah, of course.
There are over 400,000 different species of plants.
Would all plants respond the same way to that effect?

[Student] No.

And as plants are the foundation or the basis for life on the planet, for they’re the bottom of the food chain, are there gonna be ramifications of that? Oh, hell yes!

Here’s one of them, I got this from the ExxonMobil website.

Now that provides strength but this is lovely fine.

And you can see lovely fine you can (mumbles).

Well look at that, that is so cool.

I’ve only find Rosemary when you give it more carbon dioxide.

This is an invasive vine and it also responds to carbon dioxide.

Wow, this is one of the worst weeds in the United, am sorry, I keep saying weeds,
the current administration term is alternative crop.
So I don’t wanna confuse anybody, okay?
All right, so this also responds to carbon dioxide.
Well what are the consequences of this direct effect of rising CO2?
Well, it’s a fundamental resource for plant growth and all plants are gonna be beneficial to human society.
Not all plants respond the same way and rising CO2 alters the qualitative components of plants.
Nobody talks about this because CO2 is plant food and everything is wonderful and good, doesn’t work that way.
So let’s look at the good.
Let’s take the good part first, all right?
All of you are familiar with malaria.
It’s a tremendous and awful storage disease. So, one of the ways in which it is dealt with is through this particular plant.
This is Artemisia annua or sweet Annie, okay?
It has been used in Chinese medicine for hundreds of years as a means to combat malaria.
It produces this compound artemisinin which has this wonderful peroxide bridge which is important in terms of killing Plasmodium,
the carrier for malaria. So, it is part of what are considered to be artemisinin combination therapies which is still the primary means to respond to malaria globally. 

And what they do in this is they take artemisinin compounds, they add different one or two longer acting drugs, usually from the quinine family, they add it to the artemisinin and that’s a means to prevent or help you get over the malaria.

And just from a sort of anatomical point of view, the glandular secretion, the trichomes in artemisia when you have a little closer look, that’s where your artemisinin is being produced.

So obviously, the question I gotta ask is, if CO2 stimulates plant growth, what does it do for artemisinin production? And we worked with a group at Nanjing University at the National Academy, the Chinese Academy of Sciences.

And they have a FACE of free CO2 enrichment system. We were looking at the artemisinin content as a function of carbon dioxide and function of the carbon:nitrogen ratio. So you could use this elemental analysis of carbon and nitrogen as a means to predict how much our artemisinin was being produced by give a plant.
And then Chan Jiu who was my colleague there, went to different herbarium around China to look at artemisinin, to collect it and to do this C:M ratio. So we have collections that vary from 1900 to 2005, 2006. And during this time period, carbon dioxide has risen, in sort of a logarithmic fashion, slow at first and then increasing. Is there a connection between this rise in carbon dioxide and the change in the estimated artemisinin concentration produced? And we think there is. Here’s the carbon dioxide levels here in the curve, and here is the estimated artemisinin concentration that we’re seeing for this as a function of decade, as a function of carbon dioxide. In fact, what they’re doing now is that the are forwarding greenhouses where our AC is growing, adding more carbon dioxide as a means to increase artemisinin production now. So this is a good thing. It’s a way of increasing a chemical compound produced by leaves that we know has a positive effect with respect to malarial concentrations, trying to cure your malarial symptoms.
So from the good point of view, Artemisia annua by the way, is a common weed in North America, is a central pharmacological resource to treat malaria in Africa. Recent increases in atmospheric CO2 are associated with the increase of a known anti-malarial drug derived from this plant. What other plant-based drugs are responding? Don’t know? You need find out. Let me give you the bad, okay? This is something I’ve been working on for a number of years and has to do with pollen. How many of you suffer from seasonal pollen allergies? Raise your hand, excellent. Okay, so basically the plants that are associated with seasonal pollen allergies sort of fall into three major taxa; you have trees in the spring, weeds and grasses in the summertime and Ragweed in the fall. We went through and looked at how again, how is carbon dioxide affecting pollen production from ragweed during sampling of catkins. Here are some of the early work that we did, this is great chamber work where we were lowering the carbon dioxide values to pre-industrial levels and then projecting to 600.
which will almost certainly occur in the century. And this is the overall plant biomass for ragweed of the branch per plant basis.

Here’s the pollen production going for 280 to 370 double pollen production, going from 370 to 600 double as you can.

And hey, not only was an increase in growth but only increasing in terms of pollen production, but also in terms of the antigen Amb a1 based on the ELISA test where going as an increase as carbon dioxide went up as well. We haven’t been able to replicate this, by the way. So that’s another challenge for you young researchers.

That are out there. But, there’s pretty good indication that ragweed has this kind of respond. Yeah, yeah, all the interesting doctors has good interesting stuff, but it’s a chamber study. It’s a chamber study, doesn’t add any relevance in the real world.

What’s wrong with you? Okay, how do we get from the lab to the real world? Okay, well, there’s, I showed you was talking about FACE, FACE free air CO2 enrichment.

This is the Duke University FACE which was funded by the Department of Energy as we refer to it.
in federal circles, the department that everything,
you had lots and lots of money.
So this is the rain.
This is pushing in carbon dioxide
to the low valley pine forest showed you the effect
of CO2 on low valley earlier.
This is an afterward, it turns out that
plants do respond differently, you know the plant
that responded the most with this change?
Within the forest understudy?
Of course you don’t.
I’m sorry (mumbles)
There’s a problem here.
The problem for me was this cost $5 million a
year.
My entire discretionary budget at the time was
$2,000.
I could hire it for maybe five minutes,
but that’s not really gonna work.
So, I kind of like,
how do I take it from the lab,
to the real world, how do I do that?
How do I do that?
Hang on a second.
Let’s go back to the Keeling curve.
Why did they measure this in Hawaii?
I mean, I like Hawaii.
It’s got great factories.
Why would you measure carbon dioxide back-
ground in Hawaii?
- [student] High elevation
and well background carbon dioxide?

- [Lewis] Exactly.

Exactly.

So you're measuring the background carbon dioxide,

you're not measuring the carbon dioxide in the room here,

which I chose over the camp 11.

Or if I go out in the street and measure carbon dioxide.

So that gave me an idea.

Yeah, so most geological, geographically isolated spot

on Americans have high emissions,

but

maybe we could use an urban-rural transect as a means

to simulate what future environment would be like.

If I move the temperature and a carbon dioxide transect

along this line from an organic farm in Western Maryland

to downtown Baltimore, we dug the plots and moved the soil,

we made the soil uniform at the same seabed

and so the seed was the same.

We monitor all this fairly carefully.

And I'm sorry, as an academic,

I gotta show you at least one slide

that nobody in the back row can read.

So this is my contribution to that.

And so try to go through it.

This is daytime CO2, early 2000s.
It does go up with going from rural to sub-urban. Night-time temperatures go up, season light goes up the number of forestry days. Now there are some day time temperature, now there’s some concerns here. One of them is ozone. Well, it turns out that when you had an ozone, day in downtown Baltimore, within four hours, you got the same ozone occurring at the rural site. So we didn’t think that was too much of an issue. Yeah, we did get more hydrogen deposited and rainfall for the urban side relative to the rural side. But the soil that we took out to each location already had a great deal of nitrogen in it, it was firm, so from the same source. So we don’t think that was too much of a problem. So maybe we could use this. Since there we are, two meters by two meters, digging down into the soil, if you look closely, you’ll see Jenny Hopper (mumbles). Okay, so we did that. And we packed the soil, the seed bank down, we took out our railroad samplers here to monitor falling around each of the sites. And hey, cool. We got in the farm site, the rural site years when the ragweed first showed up, the pollen first showed up around day of year to sometime in September, peaked and then went down.
Okay, now, these two lines here, these two arrows, are the start of the maximum pollen based on the farm side, sort of out of control.

And you can see it if I go to the semi rural, the sub-urban areas starting earlier and maximizing the warmer when we get to the cities.

Holy cow! The individual ragweed plant in the city with more CO2 with more temperature and a longer growing seasons producing on average 10 times more pollen than the one out in the country.

Wow, okay. That was a cheap way of getting a featured climate to see what ragweed might do.

Yeah, okay, that’s interesting, but it’s a global problem here. Yeah, it’s a global climate change. How do we scale up from this?

Well, I use a very sophisticated instrument on my desk called telephone. And I called up different allergists and medical doctors and said, "Hi, you don’t know me, "but I’m a plant physiologist" from USK Oh, no, don’t hang up, don’t hang up.

"Hi, am a plant physio you don’t know me, "but would you be interested? "Oh, you would, okay, great, hang on.”
So what we did is we got allergists and other pollen counters across the central part of the United States to look and see whether there had been a change in temperature that could be associated with the change of pollen season for ragweed. Now, we didn’t look at ragweed numbers per se in terms of the amount of pollen just whether or not the season have been affected.

And so what we found was beginning in the 1990s. And if you start down here remember humidity CO2 paradigm? Right here, it’s warm and wet. We’re not expecting a big change in recent decades in terms of temperature, but it shouldn’t expand as you move northward. And that’s kind of what we saw. That now going up into the northern part of the US that from 95 to 2013 there’s hardly has been a significant increase in the ragweed pollen season. Okay, well, we’ve gone from the lab, we’ve gone to the city, we’ve gone to the country, lets do the world. Now when I called up they said, "Oh, I have a paper and PNAS, please listen to me." And they would listen. "So yeah soil paper that’s really interesting. We wanna help you."
"Great."

Okay, so started getting data this is from Turku, Finland.

One of the longest pollen seasons that we had.

This is total seasonal pollen, in terms of grains per cubic meter over time.

Reykjavik, Iceland, grains per cubic meter over time.

Kansas City, Missouri, we’ve since found out this probably not correct because it’s a long story, they got a new pollen counter, it was much better in counting pollen (mumbles).

Geneva Switzerland.

Okay, you’re seeing, if you’re seeing, I think it’s fair to say a trend here, a global trend.

So basically, we went out on a lab and looked at the change in pollen load, the amount of pollen over the end of the season as a function of different temperatures. And where there was some good significant correlations here in terms of, based on locations around the world. But all of these locations are in the northern hemisphere.

So our next goal is to go to the southern hemisphere.

And we’re working on that now, so stay tuned.

Alright, so that rising CO2 temperatures can influence pollen season falling amounts. Pollen allergenicity, we’re still not sure,
we have one laboratory data.
Maybe, maybe not, we need to do more work on that, right?
Okay.

Let’s go to the OMG part.
Right, this is...
What’s the role of carbon dioxide
if the trees are growing bigger and there’s more water
available, does that affect fire frequencies?
I don’t know.
Is it possible it’s affecting the qualitative component of the woods such as burning
the higher climate change or more CO2?
Is it affecting the air pollution pollen?
I don’t know, nobody’s said a word.
We talked about Kazoo earlier, well Kazoo when you give it
more carbon dioxide, generates more volatile organic compounds.
Has that shifted in the last 20 years of more CO2?
I don’t know.
Well, what about contact dermatitis
from something like poison ivy?
We actually know this one, I mentioned that this was the one that was growing more
in the FACE system in the deep forest.
It actually produces a more virulent form of urushiol.
You get contact dermatitis faster
when you come in contact with it.

00:27:50.900 --> 00:27:52.023 What about narcotics?
00:27:53.030 --> 00:27:54.400 We spend billions of dollars a year trying to eradicate narcotics.
00:27:57.430 --> 00:27:59.530 How is CO2, how is climate affecting where these narcotics are growing?
00:28:02.034 --> 00:28:03.117 I don’t know.
00:28:04.390 --> 00:28:06.520 What about food allergies?
00:28:06.520 --> 00:28:08.890 If I’m changing the quality of the composition of the food is it affecting the number of food allergies?
00:28:11.506 --> 00:28:13.050 I don’t know.
00:28:14.490 --> 00:28:16.250 Food safety, hey, everybody gets sick from eating food occasionally.
00:28:18.700 --> 00:28:19.850 Turns out warmer temperatures can promote pathogen infestation.
00:28:22.230 --> 00:28:24.290 Oh no, who knew?
00:28:24.290 --> 00:28:26.480 Is climate change or rise in carbon dioxide affecting food safety?
00:28:29.330 --> 00:28:30.470 I don’t know.
00:28:32.250 --> 00:28:34.490 Funding for all of these things from the federal government is, yeah.
00:28:34.490 --> 00:28:37.650 Nobody’s doing anything worse.
00:28:41.640 --> 00:28:43.120 Here’s some work we did do.
00:28:43.120 --> 00:28:46.490 This is kind of thistle highly invasive species.
00:28:46.490 --> 00:28:48.890 This is being sprayed with glyphosate, the recommended rates under ambient CO2 that’s being sprayed.
00:28:52.320 --> 00:28:55.557 with glyphosate under 650 parts per million CO2. And added absolutely no control.
00:28:59.230 --> 00:29:01.362 The reason why, is that when you give them more carbon dioxide,
there was a difference between how much would accumulate on the top and how much accumulated in the roots.

It did not, one of the things that glyphosate does is it travels, it’s systemic, it goes everywhere in the plant.

But if I have more roots, it was diluted out and roots can generate new shoots, et cetera.

So what’s the effect of carbon dioxide and climate change on pesticide usage?

Pesticide efficacy?

We know about this much.

If there is a green revolution, if there is a green new deal these are the things that we need to focus on.

Let’s work on one of these issues.

There’s not enough time to go into all of them.

Let’s look at nutrition.

And let’s look at rice.

Rice is consumed on a daily basis by about two billion people.

About 600 million people get more than 50% of their daily food intake from rice.

Rice, wheat, corn, they’re what we call the big three

that account half of the calories that you consume and I would be willing to bet all my life savings that you’re consuming at least one of them for this lunch.

There’s pretty good evidence that projected increases in CO2 reduce proteins.
Some of the first work that I did back at the International Rice Research Institute, doing open top chamber work with different temperatures. For the 94 wet season, our percent protein was about 10% of ambient CO2, we had a CO2 it dropped 9.3%, the dry season similar response in terms of temperature per se, reduced protein levels, but it did not interact with carbon dioxide to, in any kind of synergistic to reduce levels even more so it was a separate effect. The change in protein is ongoing. We looked at future changes. This is recent changes from 300 to 400 parts per million for about eight different rice lines. And here I think eight of the nine showed a decline or significant decline in protein concentration for the rice. And we had to stop this because our funding got hold when new administration came in. It’s ubiquitous, here’s some work by Taub. Here was in Texas and this is looking at annual crop staples; barley, rice, wheat, soybean, potato. This is the number of studies, average and standard deviation. This is the percent change in protein concentration
under elevated CO2 which range from about 600 to 700.

All of them declined with the exception of soybean. Soybean is a legume, that’s to say it fixes its own nitrogen.

So when you add more CO2, it’s not affected. So soybean, peanut, other leguminous plants do not show that change in terms of proteins with more carbon dioxide.

This is some work by a colleague Irakli Loladze, he went through and looked at the Sweden country of all the different elements in the context of rising CO2, the average of about 690. And what we see is that this very rapid rise in carbon dioxide is causing plants to be carbon rich, but nutrient poor across the board.

And we think there are ramifications of that. So it’s not just crops. We’re looking at at personal work that is done by me, or that is done by Augustine and all, came out recently looking at pasture grass that have been grown under elevated CO2.

And what effect this had in terms of weight being put on by the cattle. And this is a seven year average, we’re looking at ambient CO2, ambient temperature.

ambient CO2, elevated temperature
are elevated carbon dioxide to different temperatures.

20% nitrogen which is a proxy for percent protein declined significantly with more carbon dioxide. The animals put on weight, took them longer to put on the same amount of weight, they were slower growing.

So there’s pretty good evidence across the board that plants are responding by reducing protein levels.

That’s going to have ramifications in terms of human nutrition, direct consumption, but also in terms of livestock. Hey, but it’s just people food, right?

We decided to look at bees. And turns out that, you know, bees also have nutritional requirements that are important in the context of agriculture. So they get their carbs from nectar.

Understandable, so then they do this, they’re really good at it. They do the little waggle dance.

You know, the little waggle dance the bee says to the other bee, "Hey, you know if you go right behind this building, there’s a sunflower there, 20 feet to the left of the dumpster and you’ll find all the carbs you want.”

They’re really good at that. They’re not so good in terms of pollen yet pollen
is their main source of protein, they get 10 essential amino acids from the pollen that they consume. So again, we wanted to see okay well carbon dioxide is affecting protein, is this in fact affecting bee nutrition? And let’s do it from a point of view of the recent changes that occur. That’s a tough one to get to. How did we, we chose Goldenrod because Goldenrod is one of the last sources of pollen that bees see in the fall before they overwinter. I won’t go through all the machinations we did to come up with that, but it is. And so it’s important for bees before they overwinter to have a good source of protein, and one of those good sources is Goldenrod so we considered it to be a key for the species. So what I’m trying to do is sort of two lines of evidence here and I wanna give you the historical evidence first. And they got this through, this Smithsonian Natural History Museum. Now, I don’t know if you’ve ever been to DC but it’s a great place to go to, you got your dinosaurs, you got your elephants, you got your little diamonds, it’s a great place to go, right?
Okay, but here's the thing, way in the back in the basement, right next to the Ark of the Covenant, you’ll find all these, okay (mumbles) You’ll find all these plants samples, right? They go back to pre-industrial times in the 1850s, 1860s.

And those samples included Goldenrod. So we’re able to actually take the pollen, the stigmas, the reproductive parts, and to look at the carbon, hydrogen, nitrogen ratios. Nitrogen as a proxy again for protein.

This is the experimental evidence. This is some work that was done by my colleague, a scientist down in the Temple, Texas. He’s since retired but this is a really cool study, waiting kind of for guy. Kind of circle wagons that you see here. What Wayne did is, he added carbon dioxide at one end of the wagon. And because of photo-sensors and because it’s Texas where the sun’s shining all the time, by the time you got to the bottom wagon, all that carbon dioxide have been taken out. So they were looking at carbon dioxide levels pre-industrial, right 283 hundred. And we were very fortunate to have just enough goldenrod growing along that trans sector.
That we could actually look at the numbers. So here are the data. This is historical data from the Smithsonian. This is the estimated protein based on using nitrogen as a proxy. And going from the pre-industrial time to the current time, which is the beginning of the 21st century. We see about a 30% drop in the nitrogen protein content and an increase, corresponding increase in carbon and the nitrogen of that pollen. And for the experimental evidence, numbers are slightly different. There’s a lot of the sampling so the larger the bigger, but basically the same sort of response; that as you increase the carbon dioxide, you’re decreasing the amount of protein in the pollen. That has effects in terms of the health. And these are already under environmental, number of environmental stressors. How’s it affecting that? We don’t know. We’re not able to get funding to continue this work. But we think it’s a toe in the water stage we think it’s really interesting we want to do more if we can. Let’s go back to people food for a moment. And let’s look a little more deeper into rice.
This is work that was done two different FACE of free air C02 reference systems, one in Scuba Japan, which is shown here, another one in near Nanjing, China. And again, you’re going your rice, you’re ejecting carbon dioxide into a field situation. They did this, we did this under different cultivars, rice cultivars, eight different cultivars in Japan, most of the Japonica lines, some of the (mumbles) lines in China which had a wider range in terms of indica, hybrids and so forth. So the 18 different lines altogether was the percent protein. Again, this is, the differences now, were about 550 parts per million, which is the elevated 400, which is the ambient for all the lines. Percent change relative to ambient CO2, again trying to decline in protein for the rice. You look at iron and zinc, a little more scattered, but again many of the lines, showing a significant and rice overall showing a significant decrease. Now, we wanted to delve a little bit deeper and look at it in terms of the vitamin content. And we didn’t have this for all the different samples but for the Chinese ones.
So B1 vitamin, B1, B2, B5 and B9. And I haven’t had time to go through all the stats on, there’s a whole, there were significant effects in terms of all these declining as you increase the carbon dioxide, okay? And then we got this out of the blue, the response, it went up for alpha tocopherol, okay? Vitamin E went up with more CO2. So I was scratching my various body parts trying to figure out what the hell is this about? What’s going on, okay? Well, we have a working hypothesis for a possibility is definitely needed, all right? And here it is. If you look at all the different compounds, and if the compound has a lot of nitrogen in it, it seems to be selected against, whereas tocopherol which has no nitrogen actually showed a slight increase as carbon dioxide went up. The more nitrogen the compound had, this is just a ratio of the molecular weight, So vitamin B9 has, 20% of the provided vitamin B9 is nitrogen. So it follows along pretty good curve. So perking back to artemisinin. Artemisinin have no nitrogen in it, it went up with more carbon dioxide. So now we have eight points or nine points. We’re still trying to figure out.
00:40:31.200 --> 00:40:32.710 Is this real or not?
00:40:32.710 --> 00:40:35.240 We have some recent information
00:40:35.240 --> 00:40:37.490 for coffee, more coffee produces caffeine.
00:40:37.490 --> 00:40:39.090 Caffeine is a bicyclic alkaloid
00:40:39.090 --> 00:40:41.310 with a lot of nitrogen, right?
00:40:41.310 --> 00:40:44.640 So we have some initial information suggesting
00:40:44.640 --> 00:40:47.200 that caffeine is going down.
00:40:47.200 --> 00:40:49.100 I know that’s disappointing, right?
00:40:49.100 --> 00:40:50.830 Trust me when I tell you I was very disappointed,
00:40:50.830 --> 00:40:53.290 I couldn’t have gone through grad school without
00:40:53.290 --> 00:40:55.880 it. But it’s something to keep in mind.
00:40:55.880 --> 00:40:58.280 And but having said that, there was also variation
00:40:58.280 --> 00:41:01.373 among the different arabica lines that we looked
00:41:02.790 --> 00:41:07.520 All right, we tried to take all this information and
00:41:07.520 --> 00:41:09.970 say, how does it affect different countries?
00:41:09.970 --> 00:41:13.950 And we looked at it from the point of view of,
00:41:13.950 --> 00:41:15.840 depending on the economics of the country,
00:41:15.840 --> 00:41:19.700 if I’m a very poor country, I tend to consume a
00:41:19.700 --> 00:41:23.970 lot of rice. For example, as China has become, as the eco-
00:41:23.970 --> 00:41:26.040 nomic status
00:41:26.040 --> 00:41:27.647 then the less rice is being consumed
00:41:27.647 --> 00:41:30.060 and a more diverse diet is happening.
00:41:30.060 --> 00:41:32.420 So there are usually out of the Chinese I think,
00:41:32.420 --> 00:41:33.427 are the green lines here.
00:41:33.427 --> 00:41:36.030 But we looked at a number of different countries.
00:41:36.030 --> 00:41:39.703 And basically, the poorer the country,
00:41:40.820 --> 00:41:42.870 the greater the deficit for the different
00:41:43.950 -- 00:41:47.920 actually trying not to confuse myself anymore.

00:41:47.920 -- 00:41:50.240 But basically, the poorer the country,

00:41:50.240 -- 00:41:54.510 the greater the effect in terms of CO2 impacting nutritional

00:41:54.510 -- 00:41:56.510 value of the rice that’s being consumed.

00:41:57.700 -- 00:41:59.290 And then we’re trying to look at

00:41:59.290 -- 00:42:01.810 the 10 poorest countries in the world.

00:42:01.810 -- 00:42:03.460 They’re mostly agrarian.

00:42:03.460 -- 00:42:06.080 This was the food production in metric tons,

00:42:06.080 -- 00:42:07.373 million metric tons.

00:42:08.320 -- 00:42:11.090 This is the population here.

00:42:11.090 -- 00:42:13.100 And then you can see food production relative

00:42:13.100 -- 00:42:14.873 to population is declining.

00:42:17.090 -- 00:42:19.523 This is the kilograms per person per year.

00:42:20.880 -- 00:42:22.850 And we’re trying to also look at

00:42:22.850 -- 00:42:25.460 the elevated CO2 effect on protein.

00:42:25.460 -- 00:42:27.720 This is some work I’m doing with the broccoli,

00:42:27.720 -- 00:42:30.800 where he spent a sort of an estimate

00:42:30.800 -- 00:42:34.390 on the effect in terms of protein for these other

00:42:34.390 -- 00:42:37.610 staples, some of the staples are, that are dominant in these

00:42:37.610 -- 00:42:40.120 countries to solve the maize, potatoes, rice,

00:42:40.120 -- 00:42:42.020 or sweet potatoes, but again...

00:42:43.300 -- 00:42:46.750 First, sorghum used to try much but there’s a lot of

00:42:46.750 -- 00:42:48.860 decline in terms of protein concentration

00:42:48.860 -- 00:42:50.423 for these products.

00:42:52.610 -- 00:42:54.800 What else could be changing what’s happening to

00:42:54.800 -- 00:42:57.300 the item,

00:42:58.300 -- 00:43:00.380 of course countries we don’t really know for sure.

00:43:00.380 -- 00:43:03.460 Alright, so I didn’t really get a chance to go into
all of the things in part because there’s just not, a lot of information out there to go into. But just looking at one, the nutritional aspect, you get a sense like Oh, of just how fundamental an aspect this is and how important it can be. So plants interact by multiple means in the health of our quality, the medicine and nutrition, and maybe more than just people plants with this life. How is it going to affect in terms of having a global impact? A lot of questions to be addressed. But here’s the thing to keep in mind. If you look at it from the point of view of animals and plants, and you weigh all the animals weigh all the plants in terms of their biomass. All animals are shown here. They weigh about two gigatons. Plants constitute about two gigatons of carbon. All the rest is plants and they constitute 450 gigatons of carbon. If I affect plants, I’m going to affect every living thing on earth. And yet the CO2 as plant food mean dominates our thinking. It’s much more than that. What are the consequences? Where do we go from here? Well, we acknowledge that there’s interaction, that carbon dioxide also needs to be looked at.
We acknowledge that the potential research in the context of public health is enormous. There’s so much more that we can be doing with this. What can we do to work together? What can we do, what can we do as a means to find new opportunities, new ways that we can come together to try and find new research to do on this area that we haven’t been able to find yet. And I’m hoping that at some point, this will come to pass. So thank you all very much for your time. So now is the question time and if you have a question, just raise your hand ask it.

Yes. I know it’s a lot of information people. I know it’s not, in a way, it doesn’t contain nitrogen. So how’s that experiment you’ve done when on (mumbles) available? Yeah this is one of the things that occurred to us initially was that what we’re seeing is because of stimulation of growth, and there’s a position (mumbles) of nitrogen. So to counter that we made sure that...
we had the chamber experiment where we could really vary the amount of nitrogen but also ensure that we’re getting super amounts of nitrogen something like and is one of (mumbles).

Great work - [Lewis] Yes.

I’m sorry.

No, that’s great work.

Have people looked at sea grasses and aquatic plants?

No, not to my knowledge.

Not to my knowledge.

I’m sorry.

So, as you mentioned in your view, the cost is highly variable probably 10 hours ago. They are paid by the common practices, so, I guess that by to what extent or stage is impact of climate change will have observance of human health outcome and also using all this technology of reading, nutritious varieties and also different farming practices and also intensification to increase productivity as a to what, kind of, what can you say all these tests can help us to (murmurs) and damage to the plants?

There’s a lot in there.

So let me try and actually to address that particular number entire somehow.
But let me try and address it quickly. One of the things that we’re currently doing and nutrition is currently doing justification, we’re using what are called monocultures. The genetics of the crop that you’re growing all the same. So as you get rid of small landowners, which have more diverse genetics, and you go to bigger and bigger fields, there are different reasons for it that it becomes more and more uniform, has to be. The problem with becoming more uniform, you don’t have a diversity necessary in order to find the lines that are you could say different to their effects and CO2 and with respect to protein. That’s part of our job or it was part of our job when I was with USDA is to begin to look at these different lines and to look at how they might respond. Part of it is management and began there are different aspects of that as well, because of rising water product prices and water consumption. Flooded rice is not as grown as much as it used to be. And it has a whole nother suite of consequences that I unfortunately don’t have time to, we could talk more about it after class if you wanna know more.
is seeing two dissimilar breeding attempts.

We have farmers and breeders who are breeding for yield

and breeding for taste and breeding for insect resistance.

And as CO2 is going up in nature, we think that itself is having a selection effect.

So for example, we see wild rice, weeded rice,

is showing a much stronger response to the change,

recent changes in CO2 and cultivated absence.

And they’re actually putting more of that additional carbon dioxide into seedling for the weeded rice.

So we think that there’s an opportunity here as well.

And that is to look at the weeded rice as a means to begin to adapt, for the cultivated rice to adapt,

and to look at the both technology and genetics of the weeded rice as a means to begin to bring or adapt cultivated rice, so that it can not only respond to warm climate, but actually might benefit by it.

Okay, anybody have a cell phone?

Would you google something for me?

This isn’t about... is that okay?

Okay.

Would you google to something for me?

Would you, and this is not about rice, but just for fun,
How do you use CO2 to increase yields in your marijuana crop? I’m guessing here that if they can do that and literally they have indoor chambers and they’re doing it you know that way. But remember the CO2 has already gone up by 30%. Are we missing out on an opportunity by not taking the increase that’s already occurred and begin to find the best suited genotypes that can take that increase and divert them into seeds. I can go online, I can do this in more depth, I can find out from the marijuana industry, when to give the CO2, how much to give the CO2, what the temperature is to give the CO2, what the hormone THC I can get from the CO2 will be. Why can’t we do that for food? I would argue there’s an opportunity there. Anyway. So... Yes.
mass cyber, there isn’t any much of a research into trying to (mumbles) the decrease in vitamins and minerals in the plants and to actual public health in the past?

No, and that’s a good point. We haven’t done that yet but, that’s one of the things we’d like to work on.

We put in a convergence RFP for NSF to do that. And they turned us down.

So we, I know, we’re still on track.

I think it’s important.

You spoke about plants being carbon rich and vitamin poor, now right?

And so I can’t help but wonder if that could potentially be some contributing factor to this concurrent prevalence of obesity alongside malnutrition.

We don’t know, we think it could be,
certainly logically interpreted there’s...

it could be, but we’d like to be able to get
the numbers just to show it.

- [Student] Sure.

- [Lewis] So unfortunately, that at the moment,
it’s the Chinese folks, we just have to ignore it.

I also had another thought and maybe it’s
for everyone in the room,
just from a public health stand-point,
you know, are there...
do we know of any large ongoing sources of data
that actually, that ask about allergy, food allergy
or environmental allergy?

But this isn’t my area of research,
but does anyone know of any?
-I don’t imagine that there are databases
for food allergies that are available.
I don’t know how far back they go.
And it would be difficult thing given the other issue
in epidemiology is early exposure, and other aspects
that make it difficult to try and assess with
a separate role of climate of carbon dioxide.
But it’s a good idea.
We did, I didn’t mention this, but we did a study on peanut,
we have two different varieties of peanut
which we grew at different carbon dioxide concentrations,
and over a two year period, and one of the varieties
for both years showed an increase in Arachis stage one. Arachis is peanut genus that’s also the name of the primary allergen that peanuts produce. It’s about a 10% increase in the allergen, but the other one didn’t do anything. So it needs more work. We need to find out why is this line responding the other line not responding. What’s going on? We just don’t know.

Yes. I have kind an answer to your question. I mean, those collect technology so they have some (mumbles) from 2007, 2010. Probably just some recorded geology. And it looks like they have problem (mumbling) the categories so...

Oh, awesome, thank you.

Okay, yes, last question. That is (mumbling) though is that the total climate change mitigation challenges that mattered, is there any one focusing on the technology challenges (mumbles)? There are a number of things, for means better at the management level, but also at the genetics level and at the consumer level and we think, within the food system are ways to reduce greenhouse gas emissions.
So for example, one of the things that USDA was working on before I left was water deficit irrigation with rice. Typically, rice is flooded because it’s a way of keeping weeds down. And, but flooding rice also produces a lot of methane. And so if you change the management, you can reduce the amount of methane that’s being produced. But farmers are worried and of course, they do that, that’s going to reduce the bottom line of production. Because you can’t wag your finger at a farmer and say, "Hey, you know I’ve go this great idea that’s gonna increase your yields, "but also reduce your cost for water, "oh by the way, it’s gonna reduce the methane, "but you don’t care.” And just go, go with that. There’s lots of opportunities. What if you were a pure consumer, and you’re at the market, and you’re looking at buying a package of beef,
what if the information was there,
it says how much of my greenhouse gas feature
for buying this kind of be for us?
Yeah, you know, I could compare it to different brands
Okay, well, I’ve got three different brands
of beef here, but hey, this one’s producing much less
greenhouse gas, maybe I should buy this brand.
So yeah, there’s lots of really cool, interesting,
fun things to look at.
I mean, it’s just, it’s a question
of having the resources to do it.
Okay, thank you for this kind,
I think it was an excellent lecture.
Although we have a few, many but all of us have an interest.
